In Chad, until this study was undertaken, bovine TB was not confirmed by isolation or molecular characterization of the causative agent, *Mycobacterium bovis*. This organism is recognized as a zoonotic pathogen that infects many persons, particularly in the developing world. The highest prevalence of coinfection with bovine TB and HIV/AIDS is also in the developing world (6). Our study was aimed at isolating the first *M. bovis* isolates from specimens of Mbororo and Arab cattle in the newly setup mycobacteriology unit of the veterinary laboratory of Fracha, at characterizing the isolates with molecular methods, and at comparing the isolates with those from Cameroon (7).

The Study

From July 1 to August 31, 2002, a total of 727 of 10,000 cattle carcasses at the slaughterhouse of Farcha were condemned because of TB-like lesions on meat inspection. The overall prevalence of suspect lesions was 7.3%. A significantly higher (p = 0.04) proportion of lesions was found among Mbororo (8.2%; 212/2,596) than Arab (7%; 515/7,397) cattle (8). Lesions were mainly found in the lymph nodes and lungs (Table).

Specimens from 201 affected organs (lymph node, lung, and liver) of 199 randomly selected carcasses were collected for further processing along with the following information: breed, sex, partial or total condemnation of the carcass, date of collection, and nature of specimen (8). The geographic origins of the cattle could not be evaluated as they were brought to the slaughterhouse by traders from local livestock markets. In the subsample of 199 animals, entire condemnation of the carcass in comparison to partial condemnation occurred more often among Mbororo than Arab cattle (19/75 vs. 11/124, χ², p = 0.002). A higher proportion of Mbororo cattle with bovine TB infection was also observed in Cameroon (9); this finding may indicate that Mbororo are more susceptible to *M. bovis* strains in the 2 Central African countries.

The 201 collected specimens were washed 3 times with sterile, distilled water. Tissue samples were cut into 5 or 6 pieces and put in a sterile plastic bag containing 10 mL sterile saline for homogenization. Samples were homogenized in a blender for 1 min; this process was repeated 3 times. Ten milliliters of the suspension was decontaminated in N-acetyl-L-cysteine sodium hydroxide (0.5% NALC–2% NaOH) (10), and 0.25mL was injected onto 2 Lowenstein-Jensen slants, 1 containing glyceral (0.75%) and 1 containing pyruvate (0.6%). In addition, Middlebrook 7H9 medium containing oleic acid-albumin-dextrose-catalase and PANTA (polymyxin, amphotericin B, nalidixic acid, trimethoprim, azlocillin) were injected...
with 0.5mL of the decontaminated suspension. Injected media were incubated at 37°C (without CO₂) for 8 weeks. Growth of mycobacteria was confirmed by smear (stained by the Ziehl-Neelsen method) and acid-fast–positive colonies were subcultured. Three biochemical tests (11) were used to distinguish between _M. tuberculosis_ complex and nontuberculous mycobacteria. Results were confirmed by real-time polymerase chain reaction (10).

Overall, _M. bovis_ was isolated from more than one fourth of tissue samples and in 42% of all positive cultures. Significantly more _M. bovis_ isolates were obtained from Mbororo zebu (30/75) than from Arab zebu (26/124) (p = 0.004). The difference remained significant when the type of condemnation and type of organ were included in a multivariate logistic regression model.

Spoligotyping, as described (12), was used as a tool for identifying _M. bovis_ within the _M. tuberculosis_ complex (lack of spacers 3, 9, 16, and 39–43) but also yielded insights into the epidemiology of _M. bovis_. In total, 12 different spoligotypes were found among the 55 _M. bovis_ isolates; 51 (92.7%) of 55 isolates were in 8 clusters (≥2 strains), which showed a homogenous population structure (Figure).

The predominant spoligotype in our study was SP1, with a cluster of 22 strains (40%), as was the case in the study of Cameroon (7). SP1 that lacks spacer 30 corresponds to C1; 2 other clusters described in Cameroon (C1 and C5) were also found in Chad (SP2 and SP4). The finding of a high proportion of the same spoligotypes in the 2 countries indicates cross-border movement of cattle. A substantial degree of recent transmission of _M. bovis_ strains among cattle is supported by the apparently high prevalence (7%) of TB-like lesions at the slaughterhouse in N’Djaména. However, the homogeneity of bovine strains could also be due to the absence of introduction of new spoligotypes in this particular area. Certain Cameroonian clusters (C7, C8, C9, and C10) (7) were only detected in the Adamaua region, not in northern Cameroon or our Chadian study. The established measures of the Cameroonian government to prevent movement of cattle between the Adamaua and the 2 northern regions appear effective. As to other neighboring countries, a recent publication describes 15 _M. bovis_ isolates from cattle in Nigeria, and these also lack spacer 30 (13). This feature seems to be a characteristic of _M. bovis_ strains in Central Africa.

Fifteen strains (8 from Arab and 7 from Mbororo zebu) were typed with the IS6110 restriction fragment length polymorphism (14) method, of which 11 and 4 isolates contained 2 or 1 band, respectively (data not shown). Therefore, Chadian _M. bovis_ strains belong to low IS6110 copy number strains. Strains lacking spacer 30 had a band at 1.9 kb, in accordance with the findings in Cameroon (7). No association was found between the number of bands and the cattle breed. IS6110 typing indicated 6 clusters and, thus, was of lower discriminatory power than spoligotyping. In a recent study, variable number of tandem repeat typing was more discriminatory for Chadian _M. bovis_ strains than IS6110 and spoligotyping (15).

**Conclusions**

The first mycobacterial laboratory established in Chad confirmed bovine TB in Chadian herds by culturing and characterizing _M. bovis_. A high ongoing and cross-border transmission of _M. bovis_ in cattle is suspected, but further

molecular epidemiology studies are needed to analyze its modes and risk factors. The apparently higher susceptibility of Mbororo zebus to *M. bovis* infection should be followed-up with immunologic assays.
