Whole-cell pertussis vaccine was introduced in China in the early 1960s. We used standard typing methods to compare 96 *Bordetella pertussis* isolates collected before and after introduction of vaccination, during 1953–2005. The following vaccine-type alleles of the pertussis toxin (*ptx*) gene were characteristic for all prevaccination strains: *ptxA2*, *ptxA3*, and *ptxA4*. The shift to *ptxA1* occurred since 1963. All isolates collected since 1983 contained *ptxA1*. Pertactin (*prn*) allele 1, *prn1*, was predominant, although *prn2* and *prn3* have been detected since 2000. Serotypes fimbriae (*Fim*) 2 and *Fim2,3* were found in all isolates collected before 1986. During 1997–2005, *Fim3* became prevalent. Although changes in electrophoresis profiles over time were observed, the predominant profiles during 1997–2005 resembled those during the prevaccine era and those found in Europe before the 1990s. *B. pertussis* strains in China may differ from those in countries that have a long history of high vaccine coverage.

Whooping cough (pertussis) is an acute respiratory infectious disease caused by the bacterium *Bordetella pertussis*. After the whole-cell pertussis (Pw) vaccines were introduced in many countries during 1940–1960, illness and death rates from pertussis have decreased dramatically (1,2). However, pertussis remains a leading cause of vaccine-preventable deaths worldwide (1). A resurgence of pertussis has been observed in developed countries despite high vaccination coverage (3–9).

In the People’s Republic of China, vaccination against pertussis was started in the early 1960s, when 3 doses of Pw vaccine combined with diphtheria and tetanus toxoids were given at 3, 4, and 5 months of age. In 1982, a booster dose at 18 months of age was added (10,11). Pw vaccines are free of charge in China. Since 1995, acellular pertussis (Pa) vaccines containing purified pertussis toxin (Ptx) and filamentous hemagglutinin have been also introduced. However, because Pa vaccines are offered at the patient’s expense, use of these vaccines has been minimal, especially in some resource-limited areas. Although since 2007 Pa vaccines have been included in the national expanded program on immunization, Pa and Pw vaccines are still used in most provinces because of limited availability and cost of Pa vaccines. Although the reported vaccination coverage for the primary 3 doses increased with time, before the 1980s it was low. From 1983 through 2008, coverage ranged from 58% to 99% (median 93%) (Figure 1) (12).

In China, pertussis is a reportable infectious disease, and the number of reported cases has been decreasing (Figure 1). Since the 1990s, incidence has been <1 case/100,000 population (12). In China, pertussis is clinically diagnosed by physicians; laboratory methods such as culture, PCR, and serologic analysis are not used for diagnosis of pertussis. Therefore, the reported low incidence may be related to the diagnostic criteria used, suggesting substantial underreporting. Pertussis remains endemic to China (10–12), and a local outbreak was reported in April 1997.

In many countries, divergence in major antigens Ptx, pertactin (*Prn*), fimbriae (*Fim*) 2, *Fim3*, and tracheal colonization factor (*TcfA*) between the vaccine strains and circulating isolates has been reported (3,4,7,9,13–16). Furthermore, marked changes in *B. pertussis* strains have been...
found in these countries after introduction of vaccination. To learn more about the B. pertussis strains circulating in China, we used standardized typing methods to analyze and compare B. pertussis isolates collected before and after the introduction of vaccination (17).

**Materials and Methods**

**Bacterial Strains and Culture**

We tested 3 vaccine strains and 96 clinical isolates: 25 isolates from 1953–1958, 52 from 1963–1985, and 19 from 1997–2005. These 3 periods were chosen according to when Pw vaccines were introduced (1960) and when Pa vaccines were added to the vaccination program (1995). Information on vaccine strains and clinical isolates is shown in online Appendix Figure 1, www.cdc.gov/EID/content/16/11/1695-Techapp.htm) and in the online Technical Appendix (www.cdc.gov/EID/content/16/11/1695-Techapp.htm). Clinical information for patients from whom B. pertussis was isolated is not available. Vaccine strains P3s10 and CS were isolated in Beijing in 1951 (online Appendix Figure 1). Vaccine strain 18530 originated in the United States. Strains P3s10 and 18530 have been used to produce Pw vaccines since the early 1960s, and strain CS has been used to produce Pa vaccines since 1995. All B. pertussis isolates were confirmed by slide agglutination with specific antiserum to B. pertussis and B. parapertussis (Murex Diagnostics, Dartford, UK) and by PCR according to insertion sequence IS481 (18). B. pertussis strains were grown on Bordet-Gengou agar supplemented with 15% defibrinated sheep blood, incubated at 37°C for 4–5 days.

**Serotyping**

Serotyping was performed by a microtiter plate–based monoclonal agglutination assay as described (17). Monoclonal antibodies against Fim2 (NIBSC 04/154) or Fim3 (NIBSC 04/156) were used.

**DNA Sequencing**

PCR-based sequencing of 5 genes (prn, ptxA, tcfA, fim2, and fim3) was performed as described (17,19,20) with minor modifications. Nucleotide sequences were determined for the complete opening read frames of ptxA, fim2, fim3, and tcfA, and for part of prn. The same primers were used for amplification and sequencing (Table). The sequencing assays were performed with an ABI Prism 3100 DNA sequencing system (Applied Biosystems, Foster City, CA, USA), and data analysis was conducted with DNASTAR (Madison, WI, USA) software.

**Pulsed-Field Gel Electrophoresis**

Pulsed-field gel electrophoresis (PFGE) was performed as recommended (17) with minor modifications. Briefly, after the DNA plugs were treated with 50 U of XbaI (New England Biolabs, Ipswich, MA, USA), the cleaved DNA fragments were separated by electrophoresis on a 1% agarose gel by using a Chef Mapper (Bio-Rad, Hercules, CA, USA) with pulse times of 2.16–44.69 s for 24 h. The band patterns were analyzed with BioNumerics program version 4.0 (Applied-Maths, Kortrijk, Belgium). The clustering method used was the unweighted pair group method with arithmetic mean. The Pertussis Reference Laboratory of the National Institute for Health and Welfare, Turku, Finland, used PFGE to retest 53 clinical isolates, 3 vaccine strains, and international reference strain 18323 (7).

The selection criteria for the 53 isolates included at least 1 strain for 1 unique profile. If 2 strains had identical profiles, both were retested. If multiple strains represented the same profile, the strains isolated in different years or different regions were included. For PFGE, 8 international reference strains were included. The nomenclature was based on the profiles already defined for Finland (BpFINR) and Sweden (BpSR) (7,21). Profiles assigned as BpCHR have been found only among the analyzed isolates from China. A 2-sided Fisher exact test was used to compare frequencies of strain serotypes and genotypes from the 3 periods.
Alleles of \( ptxA, \) \( prn, \) \( tcfA, \) \( fim2, \) and \( fim3 \)

Vaccine strains P3s10 and CS contained \( ptxA2/prn1/tcfA1/fim2–1/fim3–1, \) whereas vaccine strain 18530 contained \( ptxA3/prn1/tcfA2/fim2–2/fim3–1. \) Among the clinical isolates, all 4 \( ptxA \) alleles (\( ptxA1, ptxA2, ptxA3, \) and \( ptxA4 \)) were found (Figure 2, panel B). However, the frequency of each allele changed over time. In the prevaccine era, 64% (\( n = 16 \)), 24% (\( n = 6 \)), and 12% (\( n = 3 \)) of isolates contained \( ptxA2, ptxA3, \) and \( ptxA4 \), respectively. The allele \( ptxA1 \) appeared in 1963 and has become predominant since then. After the 1980s, all isolates contained \( ptxA1. \)

Altogether 6 \( prn \) alleles (\( prn1, prn2, prn3, prn7, prn10, \) and \( prn11 \)) were detected. The amino acid sequences in variable regions of the 6 alleles are shown in online Appendix Figure 2 (www.cdc.gov/EID/content/16/11/1695-appf2.htm). Allele \( prn1 \) remained predominant at 81% (\( 78/96 \)) during the study period (Figure 2, panel C). No significant difference was found in the frequency of finding \( prn2 \) and \( prn3 \) in isolates collected during 1997–2005 than in those collected during 1953–1958 (\( p = 0.749 \)) and 1963–1986 (\( p = 0.0513 \)). All 7 isolates with \( prn7 \) contained \( ptxA3, \) whereas all 3 isolates with \( prn10 \) contained \( ptxA4. \) Two isolates with \( prn11 \) contained \( ptxA2. \) All 5 isolates with \( prn2 \) or \( prn3 \) contained \( ptxA1. \)

Four \( tcfA \) alleles (\( tcfA1, tcfA2, tcfA5, \) and \( tcfA9 \)) were identified. Allele \( tcfA2 \) was most common, representing 94% (\( n = 90 \)) of the isolates (online Technical Appendix). Also detected were 2 \( fim2 \) (\( fim2–1 \) and \( fim2–2 \)) and 3 \( fim3 \) (\( fim3–1, fim3–2, \) and \( fim3–4 \)) alleles. Of the 96 isolates, 90 (94%) contained \( fim2–1. \) All 6 isolates with \( fim2–2 \) were recovered during 1953–1958. Five of the 6 isolates with \( fim2–2 \) contained \( prn7. \) For the \( fim3 \) alleles, 96% of isolates were \( fim3–1. \) All 3 isolates with \( fim3–2 \) and 1 isolate with \( fim3–4 \) were recovered in 1997–2005. Identical amino acid sequences were found for \( fim3–1 \) and \( fim3–4, \) but a silent mutation at nt 87 was found for \( fim3–4. \) All 3 isolates harboring \( fim3–2 \) contained \( prn2. \)

### PFGE Profiles

Vaccine strains P3s10 and CS had an identical profile, BpCHR6, whereas vaccine strain 18530 represented BpFINR13 (Figure 3). The 96 isolates produced 27 distinct profiles, 4 of which (BpFINR9, BpSR127, BpSR23, and BpSR11) have been reported in Europe. The PFGE profiles obtained from vaccine strain 18530 (BpFINR13) and international reference strain 18323 were not detected among the isolates from China. The 6 common profiles represented 70% of isolates (41 isolates with BpCHR15, 7 with BpCHR6, 6 with BpCHR2, 5 with BpSR127, 5 with BpSR23, and 3 with BpCHR20). The PFGE profiles changed over time. Dendrogram analysis of the 27 profiles indicated that they belonged to 8 clusters. Among these clusters, 5 (clusters I–IV and VII) have been reported in Europe (5, 22, 23).

Previous studies have shown that cluster I includes international reference strain 18323 and 1 clinical isolate (21, 22). Clusters II and III include the vaccine strains and most strains that were circulating before the 1990s. Cluster
IV contains most strains currently circulating in Europe. Cluster VII, a new group, consists of some isolates collected from Finland in 2004 (23). Of the 3 clusters identified in our study, 1 consisted of 4 profiles (BpCHR1–3 and BpFIN13). Profile BpFINR13 was found only in pertussis vaccine strain 18530 (7). The strain was obtained from the United States and used as a vaccine strain in Finland and China. The second cluster contained profiles BpCHR14 and BpCHR19, and the third contained profiles BpCHR20 and BpCHR22.

In this study, 56 isolates tested belonged to cluster III (Figure 3). Cluster III contained 6 profiles (BpCHR8, BpCHR15, BpCHR17, BpFINR9, BpSR23, and BpSR127) with a minimum of 79% overall relatedness. All isolates belonging to the cluster were collected during 1963–1986 and 1997–2005. Of the 96 clinical isolates, only 2 isolates that belonged to cluster IV (IV-β) were identified; these 2 isolates had PFGE profile BpSR11. Strains with BpSR11 were first detected in France in 1996 (22) and have been prevalent in Europe since then (13). The 2 isolates with BpSR11 were recovered in 2000 and 2001 and contained prn2.

Discussion
Few B. pertussis isolates from China contained non-vaccine type alleles prn2 or prn3; those that did were found later. In many countries, the prn1 allele is found in most vaccine strains and predominated before introduction of vaccination. However, the vaccine type strains were gradually replaced by nonvaccine type strains, mainly with allele prn2, after the introduction of vaccination. The most prevalent type in modern isolates is prn2 (7,14,20,24). In Taiwan, Pw vaccines have been offered since 1954 (25). When 168 clinical isolates collected in Taiwan during 1993–2004 were analyzed, prn2 strains accounted for 39% in 1993–1996 and increased to 90% in 1998–2004. In contrast to findings for many countries with long histories of high vaccination coverage, prn2 was first found in China in 2000. The exact reasons for the low frequency of strains with prn2 and their relatively late emergence in China are not known. One explanation might be the low vaccination coverage in China before the 1980s and differences in vaccine coverage between urban and rural areas. Another reason might be the closed borders.

In Japan, divergence of Prn and Ptx between vaccine strains and circulating isolates (26–28) has been reported. Pw vaccines were introduced in Japan in 1958; the vaccine strain used was prn1/ptxA2. In 1971, reported vaccination coverage was 50% (8). In 1976, vaccination coverage dropped to only 9%, and pertussis returned. In 1981, a Pa vaccine containing Ptx and filamentous hemagglutinin was introduced in Japan (27). The strain used for production of the Pa vaccines was Tohama I (prn1/ptxA2), isolated in the 1950s. When 107 isolates collected from 1988 through 2001 were studied, the nonvaccine type prn2/ptxA1 appeared in 1994 and was found in 27%–42% of isolates from 1994 through 2001 (26). A recent study reported similar frequency (33%) of the nonvaccine type prn2/ptxA1 in Japan when 60 isolates collected during 1991–2007 were analyzed (28).

TcfA has been shown to be crucial for B. pertussis colonization (29). A total of 9 tcfA alleles have been reported
Several studies have demonstrated that serotype Fim3 is predominant in vaccinated populations, whereas serotypes Fim2 or Fim2,3 are predominant in unvaccinated populations (14,32,33). In Sweden, before 1979 when Pw vaccines were first used, 70% of circulating strains were serotype Fim3 (32). During 1979–1995, when pertussis vaccination was stopped, Fim2 started to increase and reached 64% in the early 1990s. In 1996, when general vaccination with Pa vaccines was reintroduced, prevalence of Fim2 declined and Fim3 strains emerged rapidly. In 2002 and 2003, Fim3 was found in 96% of fully vaccinated persons. In China, before introduction of vaccination, the prevalent serotypes were Fim2,3 and Fim2. After vaccination, the frequency of serotype Fim2,3 decreased and Fim2 became predominant. The possible explanation for the predominance of Fim2 strains after vaccination is that the 2 vaccine strains used in China express Fim2,3 and Fim3. The shift from serotype Fim2 to Fim3 was observed in 1998 and coincided with the introduction of Pa vaccines in this country. Pa vaccines without fimbrial antigens may have some effect on fimbrial serotypes of circulating isolates, as was observed in Sweden (32); however, the exact reason remains to be shown.

In our study, most strains from China had different PFGE profiles than did those from Europe. However, many PFGE profiles detected among the strains from China fell into the same clusters as those reported in Europe (5,22). For example, the most common profile, BpCHR15, fell into the same cluster (cluster III) as BpSR23 and BpSR127 (14). Cluster III includes most strains circulating in Europe before the 1990s (5,32). In China, strains with BpCHR15 had been prevalent during 1965–1983. Although the strains with BpCHR15 were recovered from several different regions and over 20 years, the possibility that some strains were isolated during outbreaks cannot be excluded.

The major PFGE cluster circulating in Europe since the 1990s is cluster IV (5,32). Cluster IV can be divided into 3 subgroups (α, β, and γ), the frequency of which differs among countries. However, since the late 1990s in many countries in Europe, subgroup IV-β became more prevalent than the other 2 subgroups (13). In our study, only 2 isolates with BpSR11 belonged to group IV-β, whereas no isolates fell into subgroups IV-α or IV-γ. This PFGE result correlates with genotyping results.

When we examined the association of 6 common PFGE profiles with different allele combinations, we found that of the 51 isolates with BpCHR15, BpSR23, or BpSR127, 94% contained ptxA1/prn1/tcfA2/fim2–1/fim3–1. Of the 10 isolates with BpCHR6 or BpCHR20, 100% contained ptxA2/prn1/tcfA2/fim2–1/fim3–1. Of the 6 isolates with BpCHR2, all contained ptxA3/prn7/tcfA2/fim2–2/fim3–1.

The emergence of B. pertussis strains carrying a novel allele (ptxP3) for the Ptx promoter in China has been recently observed in countries with long histories of high vaccination coverage, such as the Netherlands (34). Furthermore, all strains from the Netherlands with BpSR11 were found to carry the ptxP3 allele. In our study, only 2 isolates from China were found to have BpSR11, suggesting that ptxP3 strains are not common in China.

The limitations of this study include the small number of B. pertussis isolates collected during the study period and recent isolates collected mainly from Beijing and its surrounding area. Therefore, our data should be interpreted with caution, and more epidemiologic studies with a larger number of isolates should be conducted in this country.

In conclusion, B. pertussis strains in China may differ from those in countries with long histories of high vaccination coverage. Continuous monitoring of B. pertussis strains is needed.
Acknowledgments
We thank Yue Ma and Jingyun Li for excellent technical assistance and Dorothy Xing for providing monoclonal antibodies against Fim2 (NIBSC 04/154) and Fim3 (NIBSC 04/156).
