Genotyping was performed on isolates from 4 patients. One isolate contained the rmpA gene; 3 contained rmpA and magA genes. Three of these isolates also underwent capsule serotyping; 2 were type K1 and 1 was K2.

We found 4 additional patients infected with K. pneumoniae in 2009 who did not have invasive infections. Briefly, a 21-year-old pregnant recent emigrant from Yemen and a 35-year-old Hispanic pregnant woman each had a urinary tract infection; a 78-year-old Vietnamese man had nosocomial aspiration pneumonia in which K. pneumoniae was considered a pathogen; and a 34-year-old African American woman who was receiving mechanical ventilation had sputum transiently colonized with K. pneumoniae.

This case series confirms that the clinical syndrome of K. pneumoniae bacteremia and primary liver abscess has emerged in Alameda County. Other sites of infection included kidney, brain, lung, pleural space, neck, and mediastinum, as reported in Asia (1–4). Although K. pneumoniae infections are predominantly a community-associated phenomenon, nosocomial infections as we observed have been reported (8). Death reflected underlying disease rather than K. pneumoniae infection in this study. We present evidence that hypermucoviscous K. pneumoniae also can behave as a colonizer or low-virulence pathogen, as manifested in our patients with urinary tract infection, sputum coloniza- tion, and aspiration pneumonia.

Our K. pneumoniae isolates appear similar to those from Asia (5) with respect to in vitro susceptibility, capsule serotypes, and magA and rmpA genes. Most of our patients were Asian but of widely dispersed origin and without recent travel to Asia. The number of thrombotic complications in this series is striking. Such complications appear not to have been noted in the literature, and this finding requires further investigation. Our data show the emergence of hypermucoviscous K. pneumoniae in northern California and suggest that it might be unrecognized elsewhere in North America.

Acknowledgments

We gratefully acknowledge the clinical microbiology technologists at Alameda County Medical Center and St. Rose Hospital who enthusiastically found and evaluated the isolates. Genotyping was kindly performed by the Microbial Diseases Laboratory, California Department of Public Health.

Family Outbreak of Shiga Toxin–producing Escherichia coli O123:H–, France, 2009

To the Editor: Shiga toxin–producing Escherichia coli (STEC) is a major cause of foodborne disease in industrialized countries. We present results of the investigation of a family outbreak in France caused by a rare STEC serotype.

Surveillance of STEC infections in France since 1996 has been based on national surveillance of STEC-related pediatric hemolytic uremic syndrome (HUS) (1). On February 11, 2009, two cases of diarrhea were re- ported to a surveillance coordinator: 1 in a child with HUS and the other in that child’s sibling.

The 2 siblings, 2 and 6 years of age, had diarrhea beginning on February 4 and 5, 2009. Bloody diarrhea
LETTERS

developed in the younger child, and HUS was diagnosed on February 9. The older child had nonbloody diarrhea for 3 days and abdominal pain. Questioning of the patients’ parents identified no recent history of travel, contact with farm animals, or outdoor bathing. A food history indicated that the 2 patients had shared an undercooked ground beef burger 4–5 days before symptom onset. The patients’ parents also ate burgers from the same package (box); they did not report any gastrointestinal symptoms.

Fecal specimens of the patients were tested for STEC by direct PCR for STEC genes (stx); after which culture and identification of stx1, stx2, eae, and ehxA (hlyA) virulence genes; and serotyping with a panel of 22 serum samples were conducted as described (1, 2). Molecular serotyping was subsequently conducted on nonagglutinating strains by using the rfb–restriction fragment length polymorphism technique for O antigen (3) and sequencing of the flIC gene for H antigen (4).

A trace-back investigation was conducted for the implicated beef burgers, which were obtained from a box of 10, frozen, 100-g ground beef burgers purchased in late January 2009. The remaining beef burger in the box from which the patients had eaten a beef burger was obtained from the family’s freezer for microbiologic testing. Stored production samples from the implicated batch underwent microbiologic testing. After broth enrichment, ground beef samples were tested by PCR for stx and eae virulence genes and O antigens of serotypes O157, O26, O145, O103, and O111 (2,5,6). Subsequently, strains isolated from stx-positive and eae-positive enrichment broths were biochemically tested and underwent serotyping and PCR identification of virulence genes. Genetic relatedness of clinical and ground beef STEC strains was studied by using pulsed-field gel electrophoresis with Xbal as described (7).

A nonmotile strain of STEC stx2 eae ehxA, which was not serotypeable by the panel of 22 serum samples, was identified in fecal samples from patients and in the remaining ground beef. Molecular serotyping of clinical isolates and an isolate from the beef identified a strain of STEC O123:H2. Analysis by pulsed-field gel electrophoresis indicated that the clinical and meat isolates were genetically related (Figure). The level of STEC contamination in the meat was 30–40 CFU/g. All stored meat production samples tested were negative for STEC.

A clinical strain and a ground beef STEC strain were sent to the World Health Organization Collaborating Centre for Reference and Research on Escherichia and Klebsiella in Copenhagen, Denmark, in December 2009 for analysis. The clinical strain was confirmed as STEC O123:H–, and the meat strain was confirmed as a nonmotile STEC rough type by serum agglutination. Both strains had virulence genes stx2a, eae, and ehxA (F. Schuetz, pers. comm.).

We identified a family outbreak of STEC O123:H– stx2a, eae ehxA infections associated with ingestion of undercooked ground beef. No similar cases of STEC infection were identified by active case finding. This serotype is rarely described as a cause of human clinical infection. No human
isolate of serotype O123:H– is recorded in the database of the World Health Organization Collaborating Centre for Reference and Research on Escherichia and Klebsiella (F. Scheutz, pers. comm.).

Two strains of STEC O123:H– stx2d were isolated from asymptomatic persons in Germany during 1996–2000 (8). A study in Australia in 2003 reported using a strain of O123:H– stx1 stx2 ehxA from Switzerland that had been isolated from a person with diarrhea (9).

We report foodborne transmission of STEC O123:H– that resulted in a cluster of clinical cases of infection. Eating ground beef is a well-established mode of STEC transmission, particularly for serotype O157:H7. STEC serotype O123:H– has been isolated from feces of healthy lambs and sheep in Spain (10) and in southwestern Australia (9) and is considered to be among the predominant ovine STEC serotypes in these countries.

This family outbreak shows that STEC serotype O123:H–, albeit rarely described as causing human illness, can cause severe human infection. This serotype can also cause clusters of STEC infections and be transmitted by ingestion of undercooked ground beef.

Acknowledgments
We thank Sylvie Peters, Hélène Perin, Lydie Pachtenchko-Claudet, Marie-Odile Klippenspies, Julie Hanot, Laurent Claudet, Philippe Couratier, and Valérie le Bourg for assistance with investigating this outbreak; and Flemming Scheutz for verifying serotypes and virulence genes.

Austrian Syndrome Associated with Pandemic (H1N1) 2009 in Child

To the Editor: In 1957, an American internist reported the preference of Streptococcus pneumoniae for the aortic valve and its frequent association with meningitis and pneumonia (1), an association now known as Austrian syndrome. This syndrome mainly occurs in middle-age men who have predisposing factors, such as chronic alcoholism, altered immune state, dural fistula, and ear or sinus infections.

One case of Austrian syndrome has been reported in the pediatric age group, in a 7-year-old girl in whom aortic valve endocarditis developed
