Echinostoma revolutum Infection in Children, Pursat Province, Cambodia

Woon-Mok Sohn, Jong-Yil Chai, Tai-Soon Yong, Keeseon S. Eom, Cheong-Ha Yoon, Muth Sinuon, Duong Socheat, and Soon-Hyung Lee

To determine the prevalence of helminthic infections in Pursat Province, Cambodia, we tested fecal specimens from 471 children, 10–14 years of age, in June 2007. The prevalence of infection with echinostome flukes ranged from 7.5% to 22.4% in 4 schools surveyed. Adult worms were identified as Echinostoma revolutum.

Echinostomes (family Echinostomatidae) are intestinal trematodes of birds and mammals, including humans. Echinostomiasis can result in severe epigastric or abdominal pain accompanied by diarrhea, easy fatigue, and malnutrition (1). Heavy worm loads may lead to death due to intestinal perforation or marked malnutrition and anemia, as has been reported for infection caused by an echinostome species, Artyfechinostomum malayanum (under the name Artyfechinostomum mehraii), in India (1).

A total of 20 species of echinostomes that belong to 8 genera (Echinostoma, Echinocotamus, Acanthoraphyum, Artyfechinostomum, Episthmium, Himasthla, Hypoderma, and Isthmiophora) infect humans worldwide (1). Echinostoma revolutum, the most widely distributed species, is found from Asia and Oceania to Europe and the Americas (1). The first reported human infection was in Taiwan in 1929 (2). The prevalence of E. revolutum flukes in Taiwan during 1929–1979 varied from 0.11% to 0.65% (3). Small E. revolutum–endemic foci or a few cases of human infection were discovered in the People’s Republic of China, Indonesia, and Thailand until 1994 (4,5). However, no information is available about human E. revolutum infection after 1994, even in areas where the parasite was previously endemic.

In Cambodia, humans are commonly infected with intestinal nematodes and protozoa, including hookworms, Strongyloides stercoralis, Ascaris lumbricoides, Trichuris trichiura, and Giardia lamblia (6,7). However, with the exception of the blood fluke Schistosoma mekongi, infection with trematodes or cestodes has seldom been reported (8). Echinostomatid eggs have been detected in schoolchildren in 2 provinces, Battambang and Kampongcham (9,10), but adult worms were not collected for identification. The Korea Association of Health Promotion, South Korea, and The National Institute of Malaria, Entomology, and Parasitology, Ministry of Health, Cambodia, have been conducting an international collaboration to control intestinal helminthiases in schoolchildren in Cambodia (2006–2011). In June 2007, we conducted a fecal survey in 4 primary schools in Pursat Province, Cambodia, and found that an average of 11.9% of schoolchildren had positive test results for echinostome eggs. Adult worms recovered after the children received treatment with praziquantel and underwent purgation with magnesium salts were identified as E. revolutum. We report echinostomiasis as an endemic trematode infection among schoolchildren in Pursat.

The Study

The surveyed areas were lakeside (the Tonle Sap Lake) villages in Pursat Province (Figure 1) where ≈12,000 persons, including 3,500 schoolchildren, live. For this study, 471 children (237 boys), 10–14 years of age, from 4 primary schools were selected. One fecal sample from each child was collected in June 2007. Samples were transported to the Malaria Station in Pursat within 2–3 days of collection and stored at 4°C until examination. The Kato-Katz thick...
DISPATCHES

smear technique was used to detect helminth eggs. Examination of feces and anthelmintic treatment were officially approved by the Ministry of Health, Cambodia, under the agreement of the Korea-Cambodia International Collaboration on Intestinal Parasite Control for Schoolchildren in Cambodia.

Four children who had positive test results for echinostomatisid eggs and who had occasional, vague abdominal pain and discomfort were selected for anthelmintic treatment and adult worm recovery at the Malaria Station. After we obtained consent from their parents and the school guardian, the children’s infections were treated with a single oral dose of 10 mg/kg praziquantel (Shinpoong Pharmaceutical Co., Seoul, South Korea), and purged with 20 g magnesium sulfate. Whole diarrheic feces were collected 3–4 times and pooled individually. The diarrheic feces were processed as previously described (3–4). Echinostomiasis is not only an endemic infectious disease in Asian countries, including Cambodia, but also can be imported by overseas travelers from the United States or Europe. An outbreak of echinostomiasis was reported among US travelers returning from Kenya and Tanzania, although the source of infection was uncertain (12). This diagnosis should also be considered in patients with abdominal pain and diarrhea who have traveled to Southeast Asia and eaten snails or clams.

Despite the dangerous nature of echinostomes, the study of echinostomiasis has been neglected for many decades (13,14), possibly because physicians and laboratory personnel lack knowledge about this trematode parasite. In addition, no easy diagnostic technique is available to detect

* Determined by examination of feces using the Kato-Katz technique. Boldface indicates significant differences between schools A and B (p = 0.01); A and C (p = 0.004); and A and D (p = 0.004), as analyzed by z test. CI, confidence interval.
† Most of these are presumed to be eggs of Echinostoma revolutum worms.
‡ Includes eggs of Enterobius vermicularis (schools A and B) and Hymenolepis nana (school C) worms.
§ Total no. of schoolchildren positive for >1 helminth species.

Conclusions

Of the schoolchildren living near Tonle Sap Lake, Pursat Province, Cambodia, who participated in this study, 7.5%–22.4%, depending on school, were infected with E. revolutum. E. revolutum trematodes are endemic parasites in this area of Cambodia and a likely source of infection is freshwater snails or clams from the lake. The public health significance of echinostomiasis and educational and prevention efforts should be highlighted.

Echinostomiasis is not only an endemic infectious disease in Asian countries, including Cambodia, but also can be imported by overseas travelers from the United States or Europe. An outbreak of echinostomiasis was reported among US travelers returning from Kenya and Tanzania, although the source of infection was uncertain (12). This diagnosis should also be considered in patients with abdominal pain and diarrhea who have traveled to Southeast Asia and eaten snails or clams.

Despite the dangerous nature of echinostomes, the study of echinostomiasis has been neglected for many decades (13,14), possibly because physicians and laboratory personnel lack knowledge about this trematode parasite. In addition, no easy diagnostic technique is available to detect

* All children were female. Fecal samples were collected individually 2–3 hours after administration of MgSO4.
† Eggs/g of feces; amount in a typical sample was presumed to be 41.7 mg.
‡ All recovered worms were adult worms that contained eggs.
Echinostoma revolutum infection, Cambodia

Echinostome eggs, except for routine fecal examination. However, some microscopists seem to overlook or misinterpret the presence of echinostome eggs, particularly in Kato-Katz fecal smears. Even if echinostome eggs are detected, the specific diagnosis is not possible unless the adult worm is collected and identified. Thus, both the training of microscopists and emphasis on the clinical significance of echinostomiasis are urgently needed.

Acknowledgments

We thank the staffs of the National Institute of Malaria, Entomology, and Parasitology, Ministry of Health, Cambodia, for preparing the Kato-Katz smears for the schoolchildren. We also thank Hyun-Mi Kim, Yu-Jung Kim, Jae-Young Park, Geun-Hoon Lee, Hoo-Gn Jeong, and Chong-Kyun Shin, Korea Association of Health Promotion, for their help in reading Kato-Katz fecal smears.

Dr Sohn is a professor in the Department of Parasitology and Institute of Health Sciences, Gyeongsang National University School of Medicine, Jinju, South Korea. His major research area is foodborne zoonotic parasites, including echinostomes, heterophyids, and gnathostomes.
