Pulmonary Infection Caused by Mycobacterium conceptionense

To the Editor: Mycobacterium conceptionense was first identified in 2006 from a patient with posttraumatic osteitis (1). Since then, 3 more isolates have been recovered from a subcutaneous abscess (2), a wound after breast surgery (3), and an abscess after a fat injection (4). During November 2009 through April 2010, M. conceptionense was isolated from sputum from 4 patients in 2 tertiary hospitals in South Korea.

Patient 1, a 69-year-old woman, was admitted to Seoul National University Bundang Hospital in March 2010 with exacerbated dyspnea. In November 2009, CT had indicated new nodular lung lesions and chemotherapy had been started. Chest CT in 2010 showed increased size and extent of nodular infiltration, which suggested pulmonary infection rather than cancer metastasis. From 2 sputum samples, 2 isolates of M. conceptionense were identified. In addition, Streptococcus pneumoniae grew in blood and sputum cultures. Despite treatment with broad-spectrum antimicrobial drugs, the patient died of respiratory failure.

Patient 2, a 70-year-old man with Parkinson disease, was referred to Seoul National University Bundang Hospital in November 2009 for a small nodular lung lesion detected by CT during a medical checkup. He exhibited no pulmonary symptoms. Routine laboratory test results were within normal limits. M. conceptionense was isolated from sputum. Clarithromycin was prescribed for 10 days, and the patient remains asymptomatic.

Patient 3, a 70-year-old man with tongue cancer, was admitted to Seoul National University Hospital in March 2010 with exacerbated dyspnea. In November 2009, CT had indicated new nodular lung lesions and chemotherapy had been started. Chest CT in 2010 showed increased size and extent of nodular infiltration, which suggested pulmonary infection rather than cancer metastasis. From 2 sputum samples, 2 isolates of M. conceptionense were identified. In addition, Streptococcus pneumoniae grew in blood and sputum cultures. Despite treatment with broad-spectrum antimicrobial drugs, the patient died of respiratory failure.

Patient 4, a 53-year-old man, sought care at Seoul National University Hospital in 2008 for chest discomfort. Other than having diabetes mellitus, he had been healthy. Chest

with negative culture results. After discharge, he had recurrent episodes of fever, and CT showed waxing and waning pulmonary lesions. Nontuberculous mycobacteria (NTM) species were isolated from some sputum cultures: M. smegmatis in 2006; M. avium in 2007; and M. intracellulare in 2008 and 2009. In February and April 2010, her respiratory symptoms and chest CT findings indicated more severe disease, and M. conceptionense grew in sputum cultures. After treatment with clarithromycin, rifampin, and ethambutol for 2 months, the patient’s symptoms improved and sputum culture results were negative.

Patient 2, a 70-year-old man with Parkinson disease, was referred to Seoul National University Bundang Hospital in November 2009 for a small nodular lung lesion detected by CT during a medical checkup. He exhibited no pulmonary symptoms. Routine laboratory test results were within normal limits. M. conceptionense was isolated from sputum. Clarithromycin was prescribed for 10 days, and the patient remains asymptomatic.

Patient 3, a 70-year-old man with tongue cancer, was admitted to Seoul National University Hospital in March 2010 with exacerbated dyspnea. In November 2009, CT had indicated new nodular lung lesions and chemotherapy had been started. Chest CT in 2010 showed increased size and extent of nodular infiltration, which suggested pulmonary infection rather than cancer metastasis. From 2 sputum samples, 2 isolates of M. conceptionense were identified. In addition, Streptococcus pneumoniae grew in blood and sputum cultures. Despite treatment with broad-spectrum antimicrobial drugs, the patient died of respiratory failure.

Patient 4, a 53-year-old man, sought care at Seoul National University Hospital in 2008 for chest discomfort. Other than having diabetes mellitus, he had been healthy. Chest
CT showed multiple lung nodules. Sputum culture grew *M. tuberculosis*. The patient received isoniazid, rifampin, ethambutol, and levofloxacin for 6 months, during which time sputum cultures were negative. In April 2010, follow-up sputum culture grew *M. conceptionense*. The patient was asymptomatic and followed up without treatment.

Cultures for each patient were conducted at the respective hospitals, where sputum specimens were placed on solid media (Ogawa; Shinyang, Seoul, South Korea) and in liquid media (MGIT 960; Becton Dickinson, Sparks, MD, USA) after decontamination with NaOH. For all 6 specimens, acid-fast bacilli grew 4–7 days after incubation in liquid media.

Molecular identification was conducted at Seoul National University Bundang Hospital, where PCR restriction fragment length polymorphism and multiplex real-time PCR and melting curve analyses were performed as described (5,6). Each method produced identical results for all but did not support specific identification. PCR restriction fragment length polymorphism profiles and melting peaks for the isolates from patients 1–4 were similar to those of *M. septicum* and *M. fortuitum*. Sequence analyses of the 652-bp fragment of *tuf* and the 527-bp and 1,571-bp fragments of 16S rDNA genes were performed (7,8). The *tuf* sequences of isolates from patients 1, 3, and 4 showed 100% identity with the *M. conceptionense* type strain, 98.2% homology (11-bp difference) with *M. porcinum*, and 98.1% homology with *M. fortuitum*. The *tuf* sequence of the isolate from patient 2 differed by 2 bp from the others. The 16S rDNA sequence of the isolate from patient 1 showed 100% homology with sequences of *M. conceptionense* and *M. senegalense* and 99.9% (2-bp difference) homology with *M. farcinogenes*. Broth microdilution susceptibility tests for isolates from patients 1, 2, and

†Sequences of the isolates were compared with the *tuf* gene and 16S rDNA gene sequence of the type strain CIP 108544 (GenBank accession nos. EU191943.1 and AY859684.1, respectively).
‡Data modified from Thibeaut et al. (3).
4 showed susceptibility to amikacin, ciprofloxacin, clarithromycin, and doxycycline but resistance to cefoxitin, sulfamethoxazole, rifampin (MIC >16 μg/mL) and intermediate-resistance to imipenem (MIC 8–16 μg/mL).

According to the American Thoracic Society diagnostic criteria for NTM lung disease (9), patient 1 fulfilled all criteria and patient 3 fulfilled the radiographic and microbiological criteria. These findings suggest that _M. conceptionense_ can cause lung disease. For the other patients, colonization with _M. conceptionense_ is a more plausible explanation (Table).

These 4 recent cases of _M. conceptionense_ infection are in accordance with the increasing prevalence of NTM (10). Increasing prevalence might be the result of technical advances in NTM identification, including use of liquid media and sequencing, or the result of a local outbreak or contamination event. We consider contamination to be an unlikely cause because specimens were completely separated from each other during collection and testing. Isolates from different patients yielded distinct randomly amplified polymorphic DNA patterns. In conclusion, _M. conceptionense_ is not a rare NTM species in South Korea and can cause pulmonary disease.

### Mycobacterium riyadhense Pulmonary Infection, France and Bahrain

To the Editor: _Mycobacterium riyadhense_ is a newly described mycobacterial species that is potentially pathogenic for humans. Extrapulmonary infection with this nontuberculous mycobacterium (NTM) has been reported (1). We report 2 cases of pulmonary infection with this NTM.

The first case of infection was in a 39-year-old woman who was admitted to Toulon Military Hospital, Toulon, France, in December 2005 with suspected pulmonary tuberculosis. For 1 month, the patient had a persistent cough, fever, asthenia, and weight loss. Findings on chest radiographs were suggestive of tuberculosis, with cavitation in the right upper lobe, and the tuberculin skin test reaction was positive. Sputum specimens collected on 3 consecutive days were negative for acid-fast bacilli (AFB), but broth cultures (BacT/ALERT 3D system; bioMérieux, Marcy l’Etoile, France) yielded mycobacterial growth.

We used 4 multiplex line-probe assays to identify the mycobacteria: GenoType MTBC (Hain Lifescience, Nehren, Germany) identified the organisms as members of the _M. tuberculosis_ complex (MTBC; with a nonspecific reaction, banding pattern 1, 2, 3); GenoType Mycobacterium
