Antimicrobial treatments and vaccines can alter bacterial interactions in the nasopharynx, thereby altering disease processes. To better understand these interactions, we examined colonization rates of 3 respiratory bacterial pathogens among 320 children when healthy and at onset of acute otitis media (AOM). Bacterial interactions were analyzed with a repeated measures logistic regression model. Among healthy children, Streptococcus pneumoniae and Moraxella catarrhalis were synergistically (positively) associated. Colonization with S. pneumoniae when healthy, but not at onset of AOM, was competitively (negatively) associated with Staphylococcus aureus. Among children with AOM, competitive associations were found between Haemophilus influenzae and S. pneumoniae and between H. influenzae and M. catarrhalis; rates of colonization with H. influenzae were higher. Bacterial interactions result in differing pathogen prevalence during periods of health and at onset of AOM. H. influenzae might become a more common cause of AOM among children who receive pneumococcal conjugate vaccine.

Respiratory bacterial infections, including pneumonia, acute exacerbations of bronchitis, acute sinusitis, and acute otitis media (AOM) among children and adults create major clinical concerns (1,2). The most common bacteria that cause upper respiratory tract infections are Streptococcus pneumoniae, Haemophilus influenzae, and...
Moraxella catarrhalis (2). The human nasopharynx is an ecologic reservoir of these and other bacteria. A broad variety of commensal bacteria and potential bacterial pathogens colonize the nasopharynx (3,4). Colonization of the nasopharynx is a first, and essential, step toward development of respiratory bacterial infections (3). Viruses can join the microbial mix as a prelude to secondary bacterial infections of the respiratory tract (5–7).

More information about microbial interactions in the nasopharynx is needed (8). These interactions can be altered by therapeutic (e.g., antimicrobial drug) and vaccine (e.g., pneumococcal conjugate vaccination) interventions, resulting in synergistic or competitive outcomes. Information about interactions of the major bacterial respiratory pathogens in the nasopharynx and the conditions conducive to progression to infection (e.g., concurrent viral upper respiratory infections) is limited.

Microbial species can interact synergistically to promote persistence of colonization (positive, or synergistic, association) or they can compete (negative, or competitive, association) (4,9). Interactions between bacteria can alter the composition of a microbial community and affect incidence of disease (4). Several studies have reported competitive associations between colonized S. pneumoniae and S. aureus in the nasopharynx of children, raising concerns that eradication of S. pneumoniae from the nasopharynx by the heptavalent pneumococcal conjugate vaccine (PCV7) might lead to increased S. aureus colonization and subsequent infections (10–13). The introduction of the 13-valent pneumococcal conjugate vaccine will probably exacerbate this effect. Other variables that alter nasopharynx colonization patterns in children include age, gender, daycare attendance, history of having been breast-fed, environmental exposure to tobacco smoke, and otitis-prone condition (14,15).

Several recent reports have described interactions among the 3 major pathogens—S. pneumoniae, H. influenzae, and M. catarrhalis—in young children (8,10,11,16), but the results were contradictory (9). We investigated the interactions of these 3 pathogens in the nasopharynx of young children while healthy (healthy visits) and at onset of AOM (AOM visits). Our aims were to understand differences in nasopharynx colonization rates and bacterial interactions according to the child’s health status.

Materials and Methods

Study Design and Participants

We analyzed data collected during June 2006–May 2011 from children enrolled in a 5-year prospective study supported by the National Institute of Deafness and Other Communication Disorders. In that study, healthy children with no previous episodes of pneumonia, sinusitis, or AOM were enrolled at 6 months of age from 5 middle-class, suburban pediatric practices in Rochester, New York, USA. Nasopharyngeal and oropharyngeal samples were obtained from healthy children at 6, 9, 12, 15, 18, and 24 months of age and examined for S. pneumoniae, H. influenzae, M. catarrhalis, and S. aureus. If symptoms compatible with an AOM infection developed, a tympanocentesis was performed, as described, to confirm the diagnosis (17). At the time of diagnosis, nasopharyngeal and oropharyngeal samples were obtained for bacterial pathogen cultures. All children received age-appropriate standard vaccinations, including pneumococcal conjugate vaccine (PCV7) (Prevnar; Wyeth Pharmaceuticals, Collegeville, PA, USA).

We analyzed culture data from nasopharyngeal samples collected during 1,183 healthy visits and 334 AOM visits among 320 children 6–24 months of age. All samples included in this study were from children who had not received antimicrobial therapy for at least 3 weeks. Nasopharynx colonization at healthy versus AOM visits was compared among children at 6, 9, 12, 15, 18, and 24 months of age. This time frame includes peak incidence of AOM infection caused by S. pneumoniae, H. influenzae, and M. catarrhalis.

Nasopharyngeal and oropharyngeal samples were obtained for culture as described (18). The pathogens S. pneumoniae, H. influenzae, M. catarrhalis and S. aureus were isolated, and identified according to the Manual of Clinical Microbiology (19).

The study was approved by the Institutional Review Board of the University of Rochester and the Rochester General Hospital. Written informed consent was obtained from parents or guardians before the children were enrolled.

Statistical Analyses

The rates of nasopharynx colonization among children of the same age at healthy and AOM visits were compared by using the Fisher exact test and GraphPad Prism software (www.graphpad.com). Bacterial interactions were analyzed by using repeated measures logistic regression models. Predicted outcomes of colonization with S. pneumoniae, H. influenzae, and M. catarrhalis were examined by using multivariate logistic regression. Generalized estimating equations were used to model exchangeable correlation within participants (20). Two logistic regression models (1 for healthy visits and 1 for AOM visits) were calculated by using R version 2.13.2 (www.r-project.org/). To examine the effects of covariates on each of the 3 pathogens, we modeled colonization of each pathogen separately by using the remaining 2 pathogens as predictors and including the interaction term (8). Because few S. aureus were isolated, we did not separately model colonization outcome for S. aureus (8). For each model, we estimated odds ratios
(ORs) for the response pathogen given the presence of each predictor pathogen alone, then jointly; synergistic associations between bacteria are indicated by OR>1; competitive associations, by OR<1. The absence of both predictor pathogens was used as the reference condition. \( p < 0.05 \) was considered significant; \( p < 0.01 \), strongly significant; \( p < 0.1 \), weakly significant. The model was also used to estimate the OR for each pathogen relative to the risk factors of sex, age, daycare attendance, history of having been breast-fed, environmental exposure to tobacco smoke, and otitis-prone condition.

**Results**

**Polymicrobial Nasopharynx Colonization**

Differences in nasopharynx colonization rates between healthy and AOM visits remained generally similar across the longitudinal samplings (Table 1). The rate of nasopharynx colonization by *S. pneumoniae* for children of all ages at healthy visits, when neither *H. influenzae* nor *M. catarrhalis* was present, was 14.2%; this rate did not differ statistically from that at AOM visits (14.4%; \( p = 0.93 \)) (Table 1). In contrast, the rate of nasopharynx colonization by *H. influenzae* for children of all ages at AOM visits, when neither *S. pneumoniae* nor *M. catarrhalis* was present, was 19.5%; this rate was >4-fold higher than the rate at healthy visits (4.5%; \( p<0.0001 \)) (Table 1). The rate of nasopharynx colonization by *M. catarrhalis* for children of all ages at healthy visits, when neither *H. influenzae* or *S. pneumoniae* was present, was 20.6%; this rate was 2-fold higher than that for AOM visits (10.5%; \( p<0.0001 \)) (Table 1).

Polymicrobial colonization of the nasopharynx was significantly less common at healthy visits than at AOM visits. At the onset of an infection, polymicrobial colonization increased by 1.5–2.8-fold overall for children of all ages (\( p<0.05 \) for all). At healthy visits, the proportion of children with polymicrobial nasopharynx colonization was 18.1% (214/1,183); whereas at AOM visits, the proportion was 45.5% (152/334) (\( p<0.0001 \)). A comparison of single-pathogen colonization and polymicrobial colonization at ages 6, 9, 12, 15, 18, and 24 months and differences between healthy visits and AOM visits are shown in the Figure.

**Bacterial Interactions**

The predicted outcome of nasopharynx colonization with *S. pneumoniae, H. influenzae*, and *M. catarrhalis* is...
Nasopharyngeal Bacterial Interactions in Children

shown in Table 2. At healthy visits, when colonization with S. pneumoniae was the predicted outcome, S. pneumoniae was synergistically associated with M. catarrhalis colonization (OR 1.51, p = 0.0059) but not with H. influenzae colonization (OR 0.83, p = 0.49).

At onset of AOM infection, the predictions differed greatly. When colonization with S. pneumoniae was the predicted outcome, S. pneumoniae colonization was competitively associated with H. influenzae colonization (OR 0.41, p = 0.0021) and M. catarrhalis colonization (OR 0.37, p = 0.0022). When colonization with M. catarrhalis was the predicted outcome, M. catarrhalis colonization was competitively associated with S. pneumoniae colonization (OR 0.40, p = 0.0014) but not with H. influenzae colonization (OR 1.02, p = 0.94). When colonization with H. influenzae was the predicted outcome, H. influenzae colonization was competitively associated with S. pneumoniae colonization (OR 0.41, p = 0.0021) and M. catarrhalis colonization (OR 0.37, p = 0.0022). When colonization with M. catarrhalis was the predicted outcome, M. catarrhalis colonization was competitively associated with H. influenzae colonization (OR 0.35, p = 0.0015) but not with S. pneumoniae colonization (OR 1.02, p = 0.95).

The higher prevalence of a potential otopathogen in the nasopharynx need not imply greater association. For example, the marginal rates for the pathogens in the healthy group (all ages) were 0.303, 0.117, and 0.363, the product of which is 0.0129 (Table 1). The actual rate for the occurrence of all 3 is 0.028, indicating an increase in association compared with chance. In contrast, the corresponding rates for the AOM group are 0.527, 0.479, 0.434, the product of which is 0.1096, compared with an actual rate of occurrence of 0.087 for all 3, indicating a decrease in association compared with chance. These totals are therefore compatible with the ORs reported in Table 2.

Effects of Other Risk Factors on Bacterial Colonization

Analysis of the effects of S. aureus colonization and host factors on nasopharynx colonization by S. pneumoniae, H. influenzae, and M. catarrhalis in children when healthy and at onset of AOM indicated that nasopharyngeal cultures were positive for S. aureus at 7.7% (91/1,183) of healthy visits and 5.7% (19/334) of AOM visits (p = 0.23). S. aureus was competitively associated with S. pneumoniae at healthy visits (OR 0.55, p = 0.011) but not at AOM visits (OR 0.95, p = 0.89). No significant associations were identified between S. aureus and H. influenzae or between S. aureus and M. catarrhalis at either type of visit (Table 2). The healthy visits, daycare attendance was significantly positively associated with S. pneumoniae (OR 1.87, p = 0.0001) and H. influenzae colonization (OR 1.71, p = 0.015) but not with M. catarrhalis colonization (OR 1.28, p = 0.11). At onset of AOM, daycare attendance was significantly positively associated with H. influenzae colonization (OR 2.06, p = 0.0032) but not with S. pneumoniae (OR 1.29, p = 0.28) or M. catarrhalis colonization (OR 0.91, p = 0.70). The otitis-prone condition (defined as 3 episodes of AOM infection within 6 months or 4 AOM infections within 12 months) was significantly positively associated with
We found that patterns of nasopharynx colonization associations in children differed at onset of AOM and when healthy. *H. influenzae* colonization was competitively associated with *S. pneumoniae* and *M. catarrhalis* colonization at AOM visits but not at healthy visits; the rates of nasopharynx colonization by *H. influenzae* were 4-fold higher during AOM visits than during healthy visits.

Our findings suggest that during the PCV era, *H. influenzae* might increase as a bacterial pathogen of AOM. Our data among young children show that nasopharynx colonization studies of healthy children might not reflect the polymicrobial mix at the time of onset of AOM; the nasopharyngeal environment during onset of AOM favors *H. influenzae* colonization. It is the mix of bacteria at time of infection that determines which organisms are most likely to cause infection (12). We have previously shown that among children, the changes in nasopharynx colonization by *S. pneumoniae* and *H. influenzae* caused by PCV7 resulted in a remarkable proportionate decrease in AOM infection caused by *S. pneumoniae* and a proportionate increase in

§Reference.
AOM infection caused by *H. influenzae* (17,21,22). At onset of AOM, when *H. influenzae* co-colonizes with *S. pneumoniae* or *M. catarrhalis*, *H. influenzae* predominates over these 2 bacteria to cause AOM (18). The elimination of *S. pneumoniae* strains expressing PCV7 serotypes has resulted in the remaining *S. pneumoniae* strains, except serotype 19A, competing less effectively with *H. influenzae* in the nasopharynx (18). Therefore, with a further reduction in nasopharynx colonization by *S. pneumoniae*, including strains expressing serotype 19A (as will probably result from the recent introduction of PCV13 in some countries), our data suggest that *H. influenzae* might fill the nasopharyngeal niche at the onset of AOM, and consequently, *H. influenzae* might become a more prominent cause of AOM.

*S. aureus* also can cause respiratory infections; several reports have suggested that *S. aureus* might be replacing *S. pneumoniae* as a dominant nasopharynx colonizer as a consequence of the introduction of PCV. Concern has been expressed that *S. aureus* might emerge as a more prominent respiratory pathogen (10–13,23). However, our results do not support that *S. aureus* has emerged as a frequent pathogen of AOM after introduction PCV7.

Knowledge regarding interactions among *S. pneumoniae*, *H. influenzae*, and *M. catarrhalis* is limited, appears contradictory, and is confined to studies among children. Zemlickova et al. found no significant association between *S. pneumoniae* and *H. influenzae* or between *S. pneumoniae* and *M. catarrhalis* in the nasopharynx of 425 healthy children, 3–6 years of age, in the Czech Republic (11). Madhi et al. found synergistic associations between *S. pneumoniae* and *H. influenzae* in PCV9-vaccinated healthy children, 5 years of age, in South Africa (10). Jacoby et al. found synergistic associations between nasopharynx colonization by *S. pneumoniae*, *H. influenzae*, and *M. catarrhalis* in healthy children, 1–24 months of age, but no significant association between *S. pneumoniae* and *S. aureus* or between *H. influenzae* and *S. aureus* (16). At onset of respiratory viral infections and in association with AOM infection, Pettigrew et al. (8) found competitive associations between colonization by *S. pneumoniae* and *H. influenzae*, *H. influenzae* and *M. catarrhalis*, *S. pneumoniae* and *S. aureus*, and *H. influenzae* and *S. aureus* in children 6–36 months of age. Thus, our results comparing nasopharynx colonization patterns during times of health with patterns at onset of AOM help explain the prior contradictory results.

Although we found a synergistic association between *S. pneumoniae* and *M. catarrhalis* at healthy visits and a significant increase of polymicrobial colonization at AOM visits, the tendency toward polymicrobial colonization did not result in synergistic associations at AOM visits. On the contrary, competitive associations between *H. influenzae* and *S. pneumoniae* and between *H. influenzae* and *M. catarrhalis* were found at AOM visits. The increases in colonization of individual bacterial pathogens during AOM might randomly result in an increase of polymicrobial colonization and might not result from synergistic associations among the potential pathogens. Further study on the mechanism is needed.

The mechanisms to explain competitive and synergistic interactions among *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, and *S. aureus* have been explored. In a mouse model, Lysenko et al. found that when *H. influenzae* colonized with *S. pneumoniae* in the nasopharynx, *S. pneumoniae* was rapidly cleared (24). The competitive interaction was dependent on cellular components of *H. influenzae* activating the host innate immune response involving complement and neutrophils; the end result was the killing of *S. pneumoniae* (24). The mouse model results are consistent with our observations among children but differ from results observed during in vitro experiments that predict that *S. pneumoniae* should inhibit the growth of *H. influenzae* (25,26). A competitive association between *S. pneumoniae* and *S. aureus* might be mediated by *S. pneumoniae* production of hydrogen peroxide (25,27). Our results and those of others suggest that this mechanism might be active during times of health but not, on the basis of our observation, at onset of AOM (10,11,13,28).

We did evaluate the effects of age, sex, daycare attendance, breast-feeding history, exposure to tobacco smoke, and an immunologically driven increased susceptibility to AOM (15,29) in our study population. The results differed at healthy versus AOM visits except for the effect of daycare attendance on *H. influenzae* colonization; daycare attendance had a positive association with *H. influenzae* colonization at both healthy and AOM visits. Others have shown daycare attendance to be consistently associated with increased colonization by *S. pneumoniae*, *H. influenzae*, and *M. catarrhalis* in healthy children and in children with viral upper respiratory infections (8). Our previous studies have shown that children who are prone to otitis have much weaker immune responses to *S. pneumoniae* surface antigens than those who are not prone (15,30). We therefore assessed the otitis-prone condition as a predictor in the models in this study. We found that the otitis-prone condition was positively associated with *S. pneumoniae* and *H. influenzae* colonization at healthy visits but not at AOM visits.

The rates of nasopharynx colonization with *S. pneumoniae*, *H. influenzae*, and *M. catarrhalis* and the mix at onset of AOM that we observed occurred mostly in the context of a concurrent viral upper respiratory tract infection. A limitation of our study is that we did not evaluate bacterial–viral interactions. Revai et al. (31) and Chonmaitree et al. (32) found that among young children, viral upper respiratory tract infections preceded >90% of
AOM infections. At onset of AOM, 93% of the children in our study had clinical signs of a viral upper respiratory tract infection; the predominant viruses detected were influenza, parainfluenza, respiratory syncytial, and adenovirus (A. Chang, unpub. data). The culture and PCR methods used in that study did not identify rhinovirus, metapneumovirus, or bocavirus. Previous studies have shown that viral upper respiratory tract infections affect bacterial nasopharynx colonization (5,7). Respiratory viruses up-regulate epithelial cell receptors for some species of respiratory bacteria (7); they cause inflammation and down-regulate innate and adaptive host defenses (7,33). Different viruses have varying effects on different bacteria (34–36). The comparison of healthy visits with AOM visits suggests that viral infections alter the host nasopharynx environment by facilitating a shift in the polymicrobial mix and enhancing polymicrobial colonization.

We did not study the additional effect of antimicrobial drugs on nasopharynx colonization. Such treatment modifies nasopharynx colonization patterns. Pettigrew et al. (8) showed that antimicrobial drug therapy was associated with a lower prevalence of colonization with S. pneumoniae and M. catarrhalis but not with H. influenzae. Varon et al. (37) showed that colonization by S. pneumoniae, H. influenzae, and M. catarrhalis decreased after antimicrobial drug therapy; the reduction in colonization was less for H. influenzae than for S. pneumoniae or M. catarrhalis. Current national guidelines endorse the use of amoxicillin for first-line treatment of AOM, sinusitis, and community-acquired pneumonia in children (38–40). Amoxicillin is ineffective for eradicating β-lactamase–producing H. influenzae and M. catarrhalis. We have previously shown that ≈65% of H. influenzae and 100% of M. catarrhalis colonizing the nasopharynx of children in our study population elaborate β-lactamase (17,21,22). Therefore, empiric treatment with amoxicillin would probably increase H. influenzae and M. catarrhalis nasopharynx colonization in children.

Our results led us to 2 conclusions. First, nasopharyngeal bacterial interactions among S. pneumoniae, H. influenzae, and M. catarrhalis differ during health and at onset of AOM in young children. Second, at the onset of AOM, the nasopharynx environment among children vaccinated with PCV7 is favorable for H. influenzae colonization. Consequently, our results predict that H. influenzae might become a more prominent bacterial pathogen of AOM in the era of PCV. Further studies of virus–bacterium–host interactions in the nasopharynx and additional studies of the mechanisms driving the observed shifts in bacterial species and polymicrobial makeup are needed.

Acknowledgments

We thank Sally Thomas and the nurses, staff, and collaborating pediatricians from Long Pond Pediatrics, Genesis Pediatrics, Rainbow Pediatrics, Lewis Pediatrics, and Legacy Pediatrics and the parents who consented to the long and challenging study. We also thank Diana G. Adlowitz, Arthur Chang, and Jennifer Wills for assistance with pathogen identification by culture.
