Dengue is the most prevalent arboviral infection in humans (1). Since the reintroduction of dengue virus (DENV) into Brazil in the 1980s, >60% of the reported dengue cases in this region of the Western Hemisphere have occurred there (2). As the disease has become more common, unusual clinical signs, some of which involve the central nervous system, have been observed in dengue patients (2–4). We therefore assessed prevalence of dengue neurologic cases from Ceará State, Brazil, a region where dengue is endemic.

The Study

We investigated the prevalence of dengue in patients with suspected viral meningitis/meningoencephalitis in a dengue-endemic area. Cerebrospinal fluid analysis showed positive results and a 6.74× greater likelihood of identifying positive fluid in patients who died. Our findings support testing patients with neurologic manifestations for the virus in dengue-endemic areas.

Dengue meningitis was suspected when a patient had fever and symptoms of irritation of the meninges, such as headache and neck stiffness; a diagnosis of dengue meningoencephalitis was established when the patient showed signs of focal involvement of the central nervous system (CNS). A diagnosis of dengue was confirmed with a DENV-positive CSF result by reverse transcription PCR (RT-PCR), nonstructural protein (NS) 1, or IgM against DENV (3,4).

Samples were analyzed by using RT-PCR, ELISA for NS1, and IgM monoclonal antibody and a rapid immunochromatography test for IgG (3–5). Viral RNA for the nested RT-PCR was extracted from 140 μL of the CSF samples by using the QIAamp Viral RNA Mini Kit (QIAGEN, Valencia, CA, USA), following the manufacturer’s protocol, and stored at −80°C until tested. The RT-PCR for DENV was performed on 209 CSF samples, as described (5).

The NS1Ag Pan-E Dengue Early ELISA kit (Panbio Diagnostics, Brisbane, Queensland, Australia) was used to detect the dengue NS1 in 209 CSF specimens in accordance with the manufacturers’ instructions (4). The Dengue IgM Capture ELISA (Panbio Diagnostics) was performed on 209 CSF samples, according to the manufacturer’s instructions. The Panbio Dengue Duo Cassette rapid test was performed, according to the manufacturer’s instructions, with CSF specimens that were positive for DENV in any of the other tests used.

Of 209 CSF samples studied, 8 (3.8%) showed positive results in >1 test: 5 from the group admitted to São José Hospital of Infectious Disease and 3 deceased patients examined at the Fortaleza Coroner’s Office (Table 1). Reviewed literature showed that the etiologic agents of most cases of viral meningitis in Brazil are enterovirus and herpesvirus; cytomegalovirus and dengue viruses are each responsible for 10% (2/20) (6).

Conclusions

DENV as a causal agent for meningitis has been rarely reported, although some cases have been described in the
The only person of 5 with dengue fever who had signs and symptoms of a brain tumor, and 1 died. The patient who died was 52 years old, male, with a history of diabetes mellitus, hypertension, and chronic kidney disease. He presented with fever, headache, malaise, myalgia, abdominal pain, and confusion. The laboratory diagnosis on serum, not on CSF as in our study, was positive for DENV. The CSF showed 426 cells/mm³, 5% lymphocytes, 2% monocytes, 93% neutrophils, protein 136 g/L, glucose 54 g/L; recovery after 9 d.

Of 5 patients treated at São José Hospital of Infectious Diseases, 3 recovered, 1 was given a diagnosis of meningitis/meningoencephalitis, and 1 died. The patient who died was the only person of 5 with dengue fever who had signs and symptoms of a brain tumor, and 1 died. The patient who died was 52 years old, male, with a history of diabetes mellitus, hypertension, and chronic kidney disease. He presented with fever, headache, malaise, myalgia, abdominal pain, and confusion. The laboratory diagnosis on serum, not on CSF as in our study, was positive for DENV. The CSF showed 426 cells/mm³, 5% lymphocytes, 2% monocytes, 93% neutrophils, protein 136 g/L, glucose 54 g/L; recovery after 9 d.

An investigation of dengue patients with suspected CNS infection in Vietnam found 4.2% (16/378) of persons positive for DENV; 1 (0.3%) patient had meningitis (3). The frequency of finding dengue virus in patients with suspected cases of meningitis found in this study corroborated what was hypothesized in the literature: neurologic manifestations in patients with DENV have been reported in Ceará, but previous studies based laboratory diagnosis on serum, not on CSF as in our study, which indicated a relationship between dengue and CNS manifestations (8).

Of 5 patients treated at São José Hospital of Infectious Disease (Table 1), 3 recovered, 1 was given a diagnosis of a brain tumor, and 1 died. The patient who died was the only person of 5 with dengue fever who had signs and symptoms of fatal dengue hemorrhagic fever (DHF) (such as intense malaise, dry cough with dyspnea, and abdominal pain) (9). Of the 3 deceased patients (Table 1), only 1 had signs of severe dengue, including myalgia, abdominal pain, asthenia, somnolence, and confusion. Suspected cases of meningitis with other pathologic changes might also be confused with dengue cases with CNS involvement (10). Of 8 dengue patients, 2 had signs and symptoms of dengue infection. In Brazil, meningitis was confirmed for patients with oligosymptomatic dengue infection in the cities of Vitória and Rio de Janeiro (10,11).

The presence of DENV NS1 antigen (NS1Ag) has been associated with virus replication and viremia with the risk for development of DHF (12). The NS1Ag was detected in 4 of the 5 fatal cases reported here, but because none fulfilled the World Health Organization criteria for DHF, they were considered to have been cases of severe dengue because the patients died (1) (Table 1). Detection of dengue IgM in CSF has shown a high specificity (97%) for diagnosing neurologic dengue and might be associated with the neurovirulence of DENV and its ability to cause encephalitis (13). Prior to the 1996 publication of findings
The prevalence of CNS involvement in patients with dengue infection seems to vary with severity of dengue cases (11). Mortality rates also vary among studies; the reported rate of neurologic dengue was found to be 3.7% (2/54) in a study in Jamaica (7). In another study conducted in Vietnam, no patients with the neurologic form of dengue died (3); our study found a mortality rate of 1.9% (4/209). However, the proportional positivity was higher for the group of patients who died (4/27, 14.8%) than for those who recovered (4/182, 2.2%) (Table 2). The relative risk for identifying DENV-positive CSF in patients who died was 6.74× greater than that for patients who recovered (95% CI 1.79×–25.38×; p<0.0109). No patients had DHF or a concurrent condition to predict deterioration to death, thus suggesting that patients with meningitis/meningoencephalitis and DENV-positive CSF may have higher risk for development of severe forms of dengue infection.

The high risk for death among patients with dengue meningitis/meningoencephalitis in this study supports the need for increased surveillance. Dengue should be suspected in patients with neurologic manifestations in dengue-endemic areas, and appropriate treatment should be given to prevent death.

This study was supported by the Brazilian National Research Council, process MCT/CNPq 14/2009, and by the Ceará State Scientific Development Foundation, process FUNCAP 09100097-1.

Dr Araújo is a researcher in the dengue reference laboratory in the State Health Secretariat in Ceará. Her research interest and work for the past 23 years is in dengue viruses in Brazil.
