Zoonotic Filariasis Caused by Novel Brugia sp.
Nematode, United States, 2011

To the Editor: Zoonotic brugian filariasis is an incidental infection of humans with Brugia spp. nematodes that primarily parasitize nonhuman vertebrates, rarely humans (1–3). In contrast to classical lymphatic filariasis caused by B. malayi and B. timori, which are found in Asia, most zoonotic Brugia infections have been reported from the northeastern United States (2,3) or South America (3). We report a case of symptomatic brugian infection in a New York City resident who had not traveled to the Eastern Hemisphere.

In 2011, a 53-year-old White man first noted tenderness and swelling behind his penis and in his right groin after having fallen 3 months earlier. The tenderness was relieved by nonsteroidal antiinflammatory drugs, but the swelling continued; an oral antimicrobial drug, prescribed for presumed cellulitis, produced no improvement. At the time of examination, the patient had no fever or other signs or symptoms. Only a 3.0-cm × 3.0-cm firm, nonfixed right inguinal nodule without warmth or tenderness was noted. Laboratory findings were remarkable for total leukocytes of 6.4 × 10⁹, eosinophilia (12%, 600 cells/mm³), decreased hemoglobin level (10.0 g/dL), and low hematocrit of 31.2%. An excisional biopsy sample revealed intralymphatic microfilaria (online Technical Appendix Figure, wwwnc.cdc.gov/EID/article/20/7/13-1654-Techapp1.pdf).

The patient had been born and raised in Champlin, Illinois, and had resided in the Bronx, New York, since 1979; he had no history of travel to filariasis-endemic regions. Characteristics of the adult worms and microfilaria were most consistent with those of Brugia spp., which was surprising because classical brugian lymphatic filariasis seems to be limited to Asia (B. malayi) and Indonesia (B. timori) (4,5). However, the adult filariae were smaller than expected for B. malayi or B. timori nematodes, prompting consideration of zoonotic filariasis (1,6). The adult worms and microfilaria seemed to be viable, although zoonotic Brugia spp. in histologic

sections often appear degenerated (1,2,6). The diameters of the adult worms were similar to those reported from South America (females 90–100 µm, males 50 µm) (7,8) rather than those from North America (females 35–75 µm, males 32–52 µm) (1). Peripheral blood was repeatedly negative for microfilaria. Serum sent to the Centers for Disease Control and Prevention (Atlanta, GA, USA) for ELISA testing for B. malayi anti-filarial IgG 4 showed optical density of 0.13, below the ELISA cutoff for filariasis.

Because morphometric information was not adequate for species identification, paraffin-embedded biopsy specimens were submitted for molecular testing. Genomic DNA extracted from paraffin-embedded tissue with the QIAamp DNA–formalin-fixed, paraffin-embedded tissue procedure was amplified by using the primer sets DiBu-F(5′ GCTAGATATGCTACCAACAAAA-3′)/ITS1 R(5′-CTCAATGCGTCTGCAATTCGC-3′) and BuF2-(5-CATTTATGCTAGATATGCTACCAAC-3′)/ITS1-R. The products were fractionated on 2% agarose gel and stained with ethidium bromide. The internal transcribed spacer (ITS) 1 PCR product (182 bp) was automatically sequenced by using the same primers used for PCR. Lasergene software (DNASTAR, Madison, WI, USA) was used to align the sequences obtained with Brugia spp. sequences deposited in GenBank; detailed sequence comparison identified the isolate as a novel Brugia (Nematoda: Onchocercidae) species closely related to B. pahangi and B. malayi (Figure). The ITS-1 sequence was submitted to the EMBL Nucleotide Sequence Database (accession no. HE856316).

Removal of an affected lymph node without additional treatment is often considered sufficient treatment for zoonotic filariases. However, for the patient reported here, persistence of inguinal swelling prompted a repeat biopsy 4 months later; the specimen again demonstrated reactive follicular hyperplasia, although no parasites were seen. Because the patient’s initial clinical signs and subsequent persistent adenopathy were reminiscent of unilateral lymphadenitis, lymphangitis, and induration that are typical of B. malayi or B. timori filariasis, and the microfilariae in the original biopsy sample appeared to be viable, we empirically prescribed a standard dosage of oral doxycycline for 6 weeks, followed by single doses of ivermectin at 400 µg/kg and 800 mg albendazole. The patient has been well, without further adenopathy or eosinophilia, for >2 years. Because adult filariae can live for >10 years, the place of acquisition cannot be stated with certainty.

The prevalence of zoonotic infection with Brugia spp. nematodes is unknown. Many reported cases are asymptomatic or diagnosed incidentally during evaluation for persistent adenopathy (1–3). Conversely, differentiation of zoonotic from classical filariasis is unlikely in disease-endemic areas; most cases published since the initial 1962 case report (1) occurred in the United States. Most case-patients were from the Northeast.
Candida auris–Associated Candidemia, South Africa

To the Editor: We noted the report by Chowdhary et al. (1) and report Candida auris as a causative agent of candidemia in South Africa, with an estimated prevalence of 0.3% (N.P. Govender et al., unpub. data). First isolated in 2009, C. auris is an emerging species associated with clinical disease (2–6). We analyzed 4 isolates submitted to the National Institute for Communicable Diseases (Johannesburg, South Africa) from 4 patients with candidemia who had been admitted to different public- and private-sector hospitals from October 2012 through October 2013.

Identification of the isolates was undertaken by using ChromAgar Candida medium (Mast Diagnostics, Merseyside, UK), Vitek-2 YST (bioMérieux, Marcy l’Etoile, France), API 20C AUX (bioMérieux), and sequencing of the ribosomal RNA gene (7). We followed by microbroth dilution susceptibility testing (8). All isolates were misidentified as C. haemulonii and Rhodotorula glutinis by Vitek-2 YST and API 20C AUX assays, respectively (Table).

Similar to the findings of Chowdhary et al., all isolates assimilated N-acetyl-glucosamine (1). With the use of the CBS-KNAW database, pairwise sequence alignment of ITS region showed 99% sequence homology to Kuwait isolates, and alignment of D1/D2 domains of the ribosomal RNA gene (7), followed by microbroth dilution susceptibility testing (8). All isolates were misidentified as C. haemulonii and Rhodotorula glutinis by Vitek-2 YST and API 20C AUX assays, respectively (Table).

Similar to the findings of Chowdhary et al., all isolates assimilated N-acetyl-glucosamine (1). With the use of the CBS-KNAW database, pairwise sequence alignment of ITS region showed 99% sequence homology to Kuwait isolates, and alignment of D1/D2 domains showed 98% homology to the Kuwait/India isolates (9). In a neighbor-joining phylogenetic tree based on ITS sequences, South Africa isolates formed a cluster with India and Kuwait isolates (online Technical Appendix Figure, http://wwwnc.cdc.gov/EID/article/20/7/13-1765-Techapp1.pdf).

Zoonotic Filariasis Caused by Novel *Brugia* sp. Nematode, United States

Technical Appendix

Figure. Histocytologic appearance of *Brugia* nematodes in 53-year-old White man from New York, USA. A) Male and female nematodes within the lymph node with reactive follicular hyperplasia and a lymphohistiocytic granulomatous infiltrate permeated by few scattered eosinophils. Hematoxylin and eosin stain, magnification ×5. B) Male (arrows) and female worms in varying longitudinal and transverse plains. Note that males are smaller than females and have a pseudocoelomic cavity containing a single reproductive tube and intestine. Females are larger and contain paired uterine tubes. Scale bar = 50 µm, hematoxylin and eosin stain, magnification ×20. C) Gravid female. The pseudocoelom is mostly occupied by 2 uterine tubes filled with developing eggs and microfilariae, and the small simple intestine. Note the thin cuticle, which becomes thickened and more prominent over the lateral cords; the low musculature consists of few muscle cells. Hematoxylin and eosin stain, magnification ×40. D) Mature microfilariae in the uterus. The arrows point out the 3 posterior nuclei. Note that the width of the microfilariae ranged from 4.5 µm to 5.5 µm. Hematoxylin and eosin stain, magnification ×100.
