High Seroprevalence of Antibodies against Spotted Fever and Scrub Typhus Bacteria in Patients with Febrile Illness, Kenya

Jacqueline W. Thiga, Beth K. Mutai, Wurapa K. Eyako, Zipporah Ng’ang’a, Ju Jiang, Allen L. Richards, John N. Waitumbi

Serum samples from patients in Kenya with febrile illnesses were screened for antibodies against bacteria that cause spotted fever, typhus, and scrub typhus. Seroprevalance was 10% for spotted fever group, <1% for typhus group, and 5% for scrub typhus group. Results should help clinicians expand their list of differential diagnoses for undifferentiated fevers.

The Study
The study protocol was approved by the Ethical Review Committee of the Kenya Medical Research Institute (SSC #1282) and the Walter Reed Army Research Institute’s Human Subject Protection Board (WRAIR HSPB #1402). All patients provided informed consent.

Serum samples were collected from patients with fever (>38°C) at 8 hospitals in 6 ecoregions of Kenya (online Technical Appendix Figure 1, http://wwwnc.cdc.gov/EID/article/20/4/14-1387-Techapp1.pdf). The samples were screened for IgG against whole-cell antigens of R. conorii for SFG, R. typhi for TG, and Karp and Gilliam strains of O. tsutsugamushi for STG as previously described (8,9). Serum samples that were reactive at 1:100 dilutions were further titrated by using 4-fold dilutions to 1:6,400.

Because scrub typhus has not been reported in Kenya, Western blot was performed to confirm specificity of the reactive serum samples, essentially as described before (5). For Western blot, 0.06 μg/well of the Otr47b antigen was applied to a 10% sodium dodecyl sulfate–polyacrylamide gel and separated by electrophoresis. The proteins were transferred to a nitrocellulose membrane (Invitrogen, Carlsbad, CA, USA). After blocking nonspecific binding at 4°C in 10% skim milk (Difco Becton, Dickinson, Franklin Lakes, NJ, USA), lanes of migrated Otr47b antigens were probed with a sheep anti-human IgG (Kirkegaard & Perry Laboratories, Gaithersburg, MD, USA) at a 1:25,000 dilution, signal visualized by chemiluminescence, and acquired on Kodak X-Ray Film (Carestream Health Inc., Toronto, Ontario, Canada).

A total of 2,225 patients 1–72 years of age (mean age 5 years) were enrolled in the study. There was no difference in the male:female ratio across age groups. Overall, 212 (10%) febrile patients were seropositive for SFG. A substantially higher prevalence rate was seen in Garissa (57/226, 25%) than in Alupe (27/176, 15%), Marigat (37/320, 12%), Malindi (9/102, 9%), Kisii (39/656, 6%), or Kisumu (43/745, 6%) (p<0.05) (online Technical Appendix Figure 2).

In all regions, most SFG-seropositive patients had titers ≥1:1,600 (38%), with the highest numbers coming from Garissa (29%, n = 23), followed by Kisumu (18%, n = 16), and Malindi (5%, n = 4) (Figure 1, panel A). Only 4/1,611 clinicians expand their list of differential diagnoses for undifferentiated fevers.
(≤1%) febrile patients were seropositive for TG: 3 patients in Malindi and 1 in Kisumu. Antibodies against STG rickettsiae were detected in 67/1401 (5%) febrile patients. The highest prevalence was seen in Marigat District Hospital (MGT), on the floor of the Rift Valley; Malindi District Hospital (MDH), on the Indian Ocean coast; Kisii District Hospital (KSI), in the Kisii highlands; and Kisumu District Hospital and Obama Children Hospital (KSM), on the Lake Victoria basin. B) For STG, MGT had the most patients with titers of 1:400 and 1:1,600 compared with ALH, MDH, KSI, and KSM.

Figure 1. Distribution of titers to spotted fever (SFG) and scrub typhus (STG) groups in patients recruited in various surveillance hospitals. A) For SFG, Garissa District Hospital (GSA), in semiarid northeastern Kenya, had more patients with higher titers compared with Alupe District Hospital (ALH), on the Kenya-Uganda border; Marigat District Hospital (MGT), on the floor of the Rift Valley; Malindi District Hospital (MDH), on the Indian Ocean coast; Kisii District Hospital (KSI), in the Kisii highlands; and Kisumu District Hospital and Obama Children Hospital (KSM), on the Lake Victoria basin.

Table 1 shows the prevalence of SFG and STG antibodies by patient age, sex, and animal contact. Female patients were 1.88 times more likely to be exposed to STG than male patients (p = 0.0169), unlike with SFG. Seroprevalence for SFG and STG increased with patients’ age (p<0.05). Having camels and dogs was positively associated with SFG (p<0.05) and having goats with STG (p<0.05).

Conclusions
Seventy-eight percent of the study population was ≥12 years of age; >50% were 5 years of age. This age weighting may have led to underreporting of seroprevalence, because seroprevalence increased with age for SFG and STG (Table). The overall seroprevalence of SFG was 10% (212/2,225), similar to the percentage reported among febrile patients in northern Tanzania (8%) (10). Substantial differences in seroprevalence were observed among patients in the surveillance hospitals in different ecoregions of Kenya (online Technical Appendix Figure 2). Patients’ land use influenced seroprevalence; the highest rates of seroprevalence were recorded among the pastoralists of Garissa and Marigat, who keep large herds of cattle, sheep, goats, and camels. In other locales with high seroprevalence rates (Alupe, Malindi, Kisii, and Kisumu), farmers practice small-scale animal husbandry. IgG titers in most seropositive patients were high (1,600–6,400), perhaps indicating patients’ repeated exposure to other homologous or heterologous SFG organisms (Figure 1, Panel A). In contrast to seroprevalence of SFG, seroprevalence of TG rickettsioses was low (4/1,611, 1%) and comparable to that reported among febrile patients in northern Tanzania (10).
Considering that STG had not been reported in Kenya, its seroprevalence was surprisingly high (67/1,401, 5%) and was highest in Marigat (28/238, 12%) (online Technical Appendix Figure 3). Marigat also had the highest number of persons with titers of 1:400 and 1:1,600 (29/243, 12%) (Figure 1, Panel B). The reported determinants for STG are presence of rodents and vectors (chigger mites, especially *Leptotrombidium deliense*) that infest areas of heavy scrub vegetation.

Exposure to scrub typhus increased with age; persons >26 years of age were more likely to be seropositive than younger persons. Similar results were reported in a study conducted in Sri Lanka (11). Scrub typhus seropositivity was associated with contact with goats, perhaps because the short dense shrubs that are forage for goats are also the habitat for Trombiculid mites. As in South Korea but not Japan (12), more girls and women were exposed to tsutsugamushi disease than boys and men, possibly because women’s culturally sanctioned activities expose them to plant tissues inhabited by chiggers.

This study had several limitations. First, the serum samples used were from a 1-time encounter with the patient (acute-phase sample only). Convalescent-phase serum samples would have better defined the cases. Second, to demonstrate the disease unequivocally, the Trombiculid mites and the infectious *Orientia* spp. will need to be identified. Last, it remains to be determined whether the findings of STG in Kenya represents spread of *Orientia* species outside the tsutsugamushi triangle (an area that includes Pakistan, Australia, Japan, South Korea, and Thailand), as reported recently (3,13), or identifies a hitherto unknown disease-endemic focus.

**Acknowledgments**

We are grateful to the patients for taking part in this study. We thank project staff, including medical officers, nurses, and laboratory technicians. This work is published with the permission of the director, Kenya Medical Research Institute.

Financial support for this study was from a grant from the Global Emerging Infection System and Division of the Armed Forces Health Surveillance Center.

At the time of this study, Ms. Thiga was a master of science student at the Jomo Kenyatta University of Agriculture and Technology. Her research interests include rickettsial diagnosis and epidemiology.

High Seroprevalence of Antibodies against Spotted Fever and Scrub Typhus Bacteria in Patients with Febrile Illness, Kenya

Technical Appendix

Technical Appendix Figure 1. Map of Kenya showing locations of various surveillance hospitals. Lake Victoria basin: Kisumu District Hospital, New Nyanza Provincial Hospital, and Alupe District Hospital. Kisii highlands: Kisii District Hospital. Semiarid, on the floor of the Rift Valley: Marigat District Hospital. Arid northeastern Kenya: Garissa District Hospital and Iftin Sub-District Hospital. Coast of Indian Ocean: Malindi District Hospital.
Technical Appendix Figure 2. Seroprevalence of IgG against spotted fever group rickettsiae in patients recruited from different surveillance hospitals in Kenya. Garissa District Hospital and Iftin Sub-District Hospital (GSA) in semiarid northeastern Kenya had the highest prevalence compared with Alupe District Hospital (ALH) on the Kenya-Uganda border, Marigat District Hospital (MGT) on the floor of the Rift Valley, Malindi District Hospital (MDH) on the Indian Ocean coast, Kisii District Hospital (KSI) in the Kisii highlands, and Kisumu District Hospital and Obama Children’s Hospital (KSM) in the Lake Victoria basin.

Technical Appendix Figure 3. Seroprevalence of scrub typhus in patients recruited from surveillance hospitals. Marigat District Hospital (MGT), on the floor of the Rift Valley, had the highest prevalence compared with Alupe District Hospital (ALH) on the Kenya-Uganda border; Garissa District Hospital and Iftin Sub-District Hospital (GSA) in northeastern Kenya; Kisumu District Hospital and Obama Children’s Hospital (KSM) on the Lake Victoria basin; Kisii District Hospital (KSI) in the Kisii highlands; and Malindi District Hospital (MDH) on the Indian Ocean coast.
