To the Editor: The genus Burkholderia, first proposed in 1992, has now expanded to consist of many species (1). Bacteria of this genus exhibit extensive ubiquity; they have been isolated from human, animal, and environmental sources (1-2). Although rare, Burkholderia fungorum has been implicated in several human infections (2-4). We isolated B. fungorum from the synovial tissue of a patient’s knee.

In February 2011, a 26-year-old man had a meniscal tear on the left knee but deferred surgery. Two years later, the same knee was injured after a fall. On November 1, 2013, the patient underwent anterior cruciate ligament reconstruction. On November 28, 2013, he underwent arthroscopy because of decreased range of motion in the knee. The patient did not have a fever, and leukocyte count and erythrocyte sedimentation rate were within reference range. The patient was obese but did not have diabetes, hypertension, or any autoimmune disease.

Arthroscopy indicated that the anterior cruciate ligament graft was intact. However, the synovial fluid was turbid, and synovial tissue infection was suspected. A synovial tissue biopsy was sent to the microbiology laboratory for culture. Test results for HIV, hepatitis B, and hepatitis C infection were negative. Fungal culture was also negative. After the tissue biopsy sample was incubated on blood agar for 48 h at an ambient temperature of 37°C, 2 different colonies grew; both showed black, yellow colonies of gram-negative rods. Vitek 2 (bioMérieux, Marcy l’Etoile, France) identified the isolates as Pseudomonas fluorescens (91% probability) and Brucella melitensis (94% probability). Because of the possible B. melitensis infection, all excess specimens and agar plates were sealed and discarded after being autoclaved. Later DNA amplification and sequencing of the bacterial 16S rDNA identified the isolates previously identified as P. fluorescens and B. melitensis as Mesorhizobium amorphae and Burkholderia fungorum (isolate BF370), respectively. The 16S rDNA sequences of BF370 (GenBank accession no. LN868266) displayed 99% similarity to B. fungorum strain DBT1 (GenBank accession no. HM113360).

Disk-diffusion tests performed according to the Clinical and Laboratory Standards Institute interpretive standards for Burkholderia cepacia (5) revealed that BF370 was sensitive to ceftazidime, meropenem, and trimethoprim/sulfamethoxazole. Additional characterization of BF370 with multilocus sequence typing (6) revealed a novel sequence type, 868. Novel alleles were found for 7 loci: atpD (allele 347), glnB (allele 409), gyrB (allele 609), recA (allele 367), lepA (allele 418), phaC (allele 319), and trpB (allele 406). Intravenous ampicillin/sulbactam (1.5 g, 3×/d) was administered to the patient from November 29, 2013, through December 13, 2013. No pus was observed at the wound, and the patient was afebrile. He did not report discomfort, and physiotherapy commenced on day 8 after surgery. Initial identification of the isolate as B. melitensis raised concern for possible laboratory transmission of this pathogen (7). The possibility of finding brucellae in the synovial tissue was not unexpected because Brucella spp. have been reported to cause joint infections (8). However, 16S rDNA sequencing confirmed the identity of the isolate as B. fungorum. This different finding suggests that commercial phenotypic identification system could sometimes be unreliable. The isolation of B. fungorum from the synovial tissue of this patient, however, is similar to an earlier case of leg tissue infection in a girl (3). A striking similarity shared between the isolates was their antimicrobial drug susceptibility profiles; each isolate was susceptible to ceftazidime, meropenem, and trimethoprim/sulfamethoxazole. A literature search revealed that B. fungorum had first been recovered from vaginal secretions and cerebrospinal fluid of 2 women (2). However, no clinical information was presented, leading to the absence of clinical descriptions of the infections.

Recently, B. fungorum was detected in a granuloma specimen from a 26-year-old patient (4). The bacteria were suspected to have been transmitted to the patient through a rose thorn puncture. Swelling did not appear until 3 years after the initial puncture, and the patient did not report pain or fever and was otherwise healthy (4). Although the clinical implication of B. fungorum infection remained unclear, recent cases (3,4) seem to suggest that the bacteria can induce fever in young children and has a lengthy incubation period before erupting.

We suspect that the patient reported here acquired B. fungorum during his initial injury, perhaps from the environment. The concurrent isolation of M. amorphae, a plant bacterium (9), is consistent with possible environmental origin of the infection. Our observations and those reported earlier (4) suggest the ability of B. fungorum to act as a slowly replicating opportunistic pathogen associated with tissue injuries. The slow replication rate of B. fungorum presumably mimics the growth characteristic...
of Burkholderia mallei, essential for the bacterium’s survival, proliferation, and evasion of host adaptive immune responses (10). Our findings suggest that an approach combining culture, 16S rDNA sequencing, and multilocus sequence typing be considered for the accurate identification of uncommon bacterial infection.

This study was supported in part by a High Impact Research–Ministry of Higher Education Grant (no. E000013-20001), the Naval Medical Research Center–Asia, and the US Department of State, Biosecurity Engagement Program (NAMRU: J-55025-75053).

Naegleria fowleri
Meningoencephalitis Associated with Public Water Supply, Pakistan, 2014

To the Editor: Naegleria fowleri, a free-living ameba, causes acute, fulminant, fatal primary amebic meningoencephalitis (PAM) in persons with history of recreational activities in warm freshwater (1,2). During 2008–2009, thirteen case-patients with PAM and no history of recreational water activity were reported from Karachi, Pakistan (3). Since then, PAM caused by domestic water exposure, nasal cleansing by using neti pots, and ablution has been reported globally (4–6). During 2014–2015, the Aga Khan University Hospital clinical laboratory in Karachi confirmed 19 PAM case-patients without history of recreational activities in warm freshwater.

Karachi has a subtropical, arid climate and long summers (March–October). The increasing number of PAM cases might be attributable to rising environmental temperatures and a dysfunctional water supply system in Karachi (7). Data indicating direct evidence of N. fowleri amebae in Karachi’s water supply are limited, but consistent annual reemergence of PAM in patients without history of recreational water exposure raises concerns about Karachi’s water supply.

In August 2014, a previously healthy 34-year-old man living in Karachi and having no recreational water exposure was admitted to the Aga Khan University Hospital with multiple episodes of vomiting, severe headache, and fever. Cerebrospinal fluid culture showed a low glucose level (46 mg/dL [reference 45–80 mg/dL]) and high levels of protein (216 mg/dL [reference 20–40 mg/dL]), erythrocytes (30 cells/mm³ [reference 0–10 cells/mm³]), and leucocytes (1,440 cells/mm³ [reference 0–5 cells/mm³]; 65% lymphocytes and 35% neutrophils). PCR confirmed presence of N. fowleri. The patient died 4 days after admission, and cerebrospinal fluid and blood cultures were negative for bacterial and fungal growth.

We investigated for presence of N. fowleri amebae in domestic water and for the patient’s possible exposure. In September 2014, we collected 23 samples from 2 water treatment plants (plants A and B), their pumping...
