Hemorrhagic fever with renal syndrome (HFRS) is caused by hantavirus and transmitted primarily by rodents (1,2). HFRS occurs worldwide, but >90% of HFRS cases have been reported in China (3). During 2006–2012, a total of 77,558 HFRS cases, including 866 deaths, were reported in China (4). Zibo City in Shandong Province, located in eastern China, has a high incidence rate of HFRS (1,5,6). We analyzed the clinical data for HFRS cases and surveyed the prevalence of hantaviruses in rodent populations in rural areas of Zibo City during 2006–2014.

The Study

Zibo City is a prefecture-level city located at 36°47′N 118°3′E (Figure 1). The city consists of 6 districts and 3 counties distributed over 5,938 km² of land; the total population during the 2010 census was 4.53 million, of whom 900,000 persons were farmers. The city is ≈42% plains in the north (http://115.238.252.51:9001/), 30% hills in the center, and 274 plains in the south, mid-sized mountains in the south, and 30% plains in the north (http://115.238.252.51:9001/). Zibo City is a prefecture-level city located at 36°47′N 118°3′E (Figure 1). Zibo City is a prefecture-level city located at 36°47′N 118°3′E (Figure 1). The city consists of 6 districts and 3 counties distributed over 5,938 km² of land; the total population during the 2010 census was 4.53 million, of whom 900,000 persons were farmers. The city is ≈42% plains in the north, 30% hills in the center, and 274 plains in the south (http://115.238.252.51:9001/).

We obtained data for HFRS patients from the Zibo Center for Disease Control and Prevention and analyzed these data with Excel 2007 (Microsoft, Redmond, WA, USA) and SPSS 16.0 software (SPSS Inc., Chicago, IL, USA) and χ² test for statistical analysis. The research protocol was approved by the human bioethics committee of the Zibo Center for Disease Control and Prevention, and all participants provided written informed consent. HFRS cases were confirmed by detection of hantavirus IgM in patients’ serum with an ELISA kit (Beijing Wantai, Beijing, China).

During 2006–2014, a total of 782 HFRS cases were reported in Zibo City; 9 (1.2%) persons died. The incidence rate of HFRS varied from 0.74 to 3.65 per 100,000 persons annually (average 1.96 cases/100,000 persons) (Table). HFRS patients were from rural areas in all 9 districts and counties in Zibo City, but most (73.3%) were from hilly areas in the central and southern parts of the city, including Yiyuan County, Zichun District, Boshan District, and Zichun District (51.8%) in the central part of the city. During 2011–2014, Yiyuan County became the major source of HFRS cases, accounting for 51.3% of all cases during this period.

HFRS cases peaked twice each year. The spring peak occurred during March–May, and the fall/winter peak occurred during October–December (Figure 2). Serum samples from 36 patients from 2006 through 2008 were typed by focus reduction neutralization test with Hantaan virus (HTNV) strain 76-128 and Seoul virus (SEOV) strain UR in Vero cells. Reducing 80% of plaques was considered a positive result (7). Focus reduction neutralization test showed that 93.4% (15/16) patients from the spring peak were infected with SEOV, and 85% (17/20) from the fall/winter peak were infected with HTNV.

The incidence for the fall/winter peak was higher than that for the spring peak for the entire city (Figures 1, 2). However, the seasonal distribution of HFRS cases varied from place to place. For example, Yiyuan County and Boshan District had a substantially higher fall/winter peak of HFRS but did not have an obvious spring peak, whereas in Zichuan District, the spring peak was higher than the fall/winter peak. The number of HFRS cases in the spring peak and fall/winter peak in the 3 high-incidence areas differed significantly (χ² = 74.40, p<0.0001).

The seasonal distribution of HFRS also varied in different years (Table; Figure 1, 2). In 2006, the spring peak was higher than the fall/winter peak, and 41.0% (64/156) of cases reported during that year occurred during March–May. In 2012, one primary peak occurred in which 73.6% (67/91) of cases occurred during the winter. In 2007 and 2010, the peak was not obvious in the spring or the fall. In 2009 and 2014, the spring peak was predominant, and the fall/winter peak was not obvious. In 2008, 2011, and 2013, the epidemic mainly occurred in the fall/winter, when incidence was much higher than for the spring peak.
The number of HFRS cases differed significantly between the spring season and fall season each year ($\chi^2 = 38.01$, $p<0.0001$).

Ages of the 782 HFRS patients ranged from 7 to 85 years (median 46 years). Most (73.8%) patients were 30–65 years of age, and more than half (51.4%) were 40–50 years of age. Most (68.4%) patients were farmers, and most (87.6%, 685/782) lived in the countryside. The male:female ratio was 2.2:1.

Of the 9 persons who died, 4 died in October, 3 died in November, and 1 each died in August and September. Five decedents were male. Decedent ages ranged from 33 to 60 years; 3 were 30–49 years of age, and 6 were 50–59 years of age. HFRS was diagnosed 3–8 days (average 5.3 days) after illness onset. The patients died 4–8 days (average 5.9 days) after illness onset.

During 2006–2014, we trapped 559 rodents with 21,384 snap-traps in residential area (inside and outside farmhouse) and in fields. The rodents’ lungs were tested for hantavirus antigen with monoclonal antibody (Shanghai Institute of Biologic Products, Shanghai, China) by direct immunofluorescence assay ($8,9$). We detected hantavirus antigens in 29 (5.2%) rodents. In residential areas, the brown rat ($Rattus norvegicus$) was the predominant rodent species and had the highest infection rate (5.3%, 21/393). The house mouse ($Mus musculus$) was next in both population and infection rate (2.4%, 1/42). Other residential rodents were all negative for hantavirus, including 16 Chinese hamsters ($Cricetulus griseus$) and 1 striped field mouse ($Apodemus agrarius$). Among field rodents, the striped field mouse was the most common species and had the highest hantavirus infection rate (11.9%, 7/59). Other field rodent species were all negative to hantavirus, including 27 brown rats, 18 buff-breasted rats ($R. flavipectus$), and 3 house mice. Infection rates for the striped field mouse, brown rat, and house

mouse did not differ significantly ($\chi^2 = 5.50, p = 0.06$). The hantavirus antigen–positive rodents were further tested by reverse transcription PCR amplification of hantavirus M segment (10) from lung tissue, and 19 rodents were PCR positive. BLAST analysis (http://blast.ncbi.nlm.nih.gov/Blast.cgi) indicated that 13 sequences belonged to SEOV and 6 belonged to HTNV. SEOV-positive rodents were all brown rats from residential areas, and HTNV-positive rodents were all striped field mice from field areas. The reverse transcription PCR–positive rate was 3.3% (13/393) for SEOV in brown rats from residential areas and 10.2% (6/59) for HTNV from field areas.

Conclusions
HFRS consistently occurred in Zibo City and peaked twice: in the spring and fall/winter. The spring peak was caused mainly by SEOV and the fall/winter peak mainly by HTNV. The major animal host of HTNV was the striped field mouse, and the major animal hosts of SEOV were the residential brown rat and house mouse. The house mouse is not considered the animal host of HTNV or SEOV, but this study and recent studies (11–13) have detected both HTNV and SEOV in this rodent. The role of the house mouse as the animal host of HTNV and SEOV needs further investigation.
