Published guidance recommends controlled movement for persons with higher-risk exposures (HREs) to communicable diseases of public health concern; US federal public health travel restrictions (PHTRs) might be implemented to enforce these measures. We describe persons eligible for and placed on PHTRs because of HREs during 2014–2016. There were 160 persons placed on PHTRs: 142 (89%) involved exposure to Ebola virus, 16 (10%) to Lassa fever virus, and 2 (1%) to Middle East respiratory syndrome coronavirus. Most (90%) HREs were related to an epidemic. No persons attempted to travel; all persons had PHTRs lifted after completion of a maximum disease-specific incubation period or a revised exposure risk classification. PHTRs enforced controlled movement and removed risk for disease transmission among travelers who had contacts who refused to comply with public health recommendations. PHTRs are mechanisms to mitigate spread of communicable diseases and might be critical in enhancing health security during epidemics.

In August 2014, the World Health Organization declared the Ebola virus disease outbreak in West Africa a public health emergency of international concern. In response to this outbreak, the Centers for Disease Control and Prevention (CDC) published Interim U.S. Guidance for Monitoring and Movement of Persons with Potential Ebola Virus Exposure, known as the Monitoring and Movement Guidance (1). This guidance recommended controlled movement, which was defined as limitation of long-distance travel by commercial means, for persons with higher-risk exposures (HREs), which were defined as having had a high-risk exposure to Ebola virus on the basis of epidemiologic risk factors or close contact with a person with symptomatic Ebola for a prolonged period who was not using appropriate personal protective equipment (1,2). In addition, in March 2015, CDC published revised criteria for use of federal public health travel restrictions (PHTRs) in the Federal Register so that these tools could be used to prevent travel of persons exposed to a communicable disease of public health concern and to support enhanced public health response to communicable disease outbreaks (Table 1) (3).

CDC uses federal PHTRs to protect the traveling public by preventing commercial air travel or other means of international travel across US borders of persons with a communicable disease or at risk for development of a disease that poses a public health threat (3,4). Federal mechanisms used to implement travel restrictions include the public health do not board (DNB) and Public Health Lookout lists (5,6). The DNB tool was developed in 2007 to prevent persons who met criteria (Table 1) from boarding commercial flights of any duration that have departures to or from the United States (5,6). A Public Health Lookout list is issued to complement the DNB, notifying US Customs and Border Protection (CBP) officers who subsequently notify CDC when a person on PHTR attempts to enter the United States at any port of entry (i.e., seaport, airport, or land border) (7). Federal PHTRs are typically not applied to domestic travel on trains, buses, or ships because the mechanism for verifying travelers on these conveyances is different than that of the robust, existing system for commercial air travel and international travel across US borders.

Federal PHTR can be considered for any persons with a suspected or confirmed disease of public health interest or a HRE to a communicable disease that poses a public health threat should the person become symptomatic during travel (5). Before the Ebola virus disease outbreak in 2014, PHTRs had only been used for persons with suspected or confirmed infectious pulmonary tuberculosis (99%) or confirmed measles (6) and not for persons at risk for development of a disease of public health interest or a HRE to a communicable disease.
Travel Restrictions and Communicable Diseases

**Table 1. Criteria for placement on and removal from federal public health travel restrictions, March 2015**

*Criteria were obtained from the Centers for Disease Control and Prevention (3).*

Of those placed under PHTR, 136 (85%) were removed after completion of the incubation period (14 days for infection with MERS-CoV, 21 for Ebola and Lassa fever) on the basis of the last day of exposure and after...
confirmation that they remained asymptomatic. Another 20 (13%) were removed because of a revised exposure risk classification after a change in guidance, and 4 (2%) were removed because of a revised exposure risk classification based on reassessment. Ebola contacts were on PHTR for an average of 12 days, MERS-CoV contacts 9 days, and the Lassa fever contacts 13.5 days. None of the persons on PHTR attempted to travel into, out of, or within the United States.

**Persons Exposed to Ebola in the United States**

Most (128, 88%) persons eligible for PHTR for an Ebola exposure were exposed to 1 of 4 cases of Ebola virus disease identified in the United States: 2 imported cases and 2 locally acquired cases (11–13) (Table 3). During October 7–November 2014, a total of 124 (97%) contacts were placed on PHTR (Figure).

The state health department (SHD) of jurisdiction identified 53 contacts for the first Ebola case-patient, who had traveled from Liberia to the United States before becoming symptomatic. Controlled movement was indicated for all contacts, and 50 (94%) were subsequently placed on PHTR; 3 (6%) contacts were not placed on PHTR because their 21-day monitoring period was scheduled to end 1 day after they were identified as needing travel restrictions. Of the 50 contacts who were placed on PHTR, 49 (98%) were healthcare workers who were assessed as high-risk contacts because of an unidentified breach in infection control in the healthcare facility where the first case-patient was treated. One community contact was considered to have had close contact with the case-patient. This contact was placed on PHTR because the person had imminent travel plans but could not be located, and it was unknown whether the person was symptomatic. None of the 50 contacts showed development of symptoms of Ebola.

Two healthcare workers who provided care to the first case-patient became the second and third confirmed Ebola case-patients in the United States (11, 12). Two SHDs identified 72 contacts who were eligible for PHTR because of their potential exposure to Ebola: 24 contacts of the second case-patient and 48 contacts of the third case-patient. A total of 71 (99%) persons were placed under PHTR; 1 person was not placed because of insufficient identifying information.

Of persons placed on PHTR, 37 (52%) were high-risk contacts and 34 (48%) were identified as having close contact. Among high-risk contacts, 31 (84%) were healthcare workers who had provided care to the second or third case-patients and 6 (16%) were community contacts. Of the 34 contacts initially identified as having close contact, 24 (71%) were removed from PHTR within 1 h after it was determined that their exposure risk classification had changed. Of these 24 contacts, 4 were reclassified after further epidemiologic assessment, and 20 were reclassified after revision of the risk classification guidelines (14). Of the contacts for the second and third case-patients who remained on PHTR for the duration of their incubation periods (47, 66%), none showed development of symptoms of Ebola.

*High risk was defined as being within ≤3 feet (1 m) of a person with symptomatic Ebola for a prolonged period while not using appropriate personal protective equipment.
†Includes 20 contacts with persons on airplanes.
‡Two healthcare workers and 1 community contact with an exposure to case-patient 1 were not placed on travel restrictions because their 21-d incubation periods were scheduled to end 1 day after they were to be placed under travel restrictions. One community contact exposed to case-patient 3 was not placed on travel restrictions because of insufficient biographical data needed for placement.
In October 2014, a fourth case of Ebola diagnosed in the United States was reported in a healthcare worker who had returned from West Africa (13); this case was not related to the other cases. The health department identified 3 high-risk contacts: 2 in the community and 1 in the household of the case-patient. All contacts were placed on PHTR and remained asymptomatic.

**Persons Exposed to Ebola Outside the United States**

Four contacts located outside the United States were identified and placed under PHTR because of exposures to Ebola cases in West Africa. Two contacts were household contacts of a deceased patient with Ebola in West Africa; the contacts had confirmed commercial travel scheduled to the United States during their 21-day incubation periods. Both contacts were removed from PHTR immediately after their incubation period, and we confirmed that neither contact became symptomatic. In addition, 2 HRE contacts were reported to CDC by foreign ministries of health (MOHs) and placed under PHTR because they reportedly had planned commercial air travel before completing the monitoring period. None of these contacts attempted to travel to the United States while on PHTR.

During December 2014–April 2015, a total of 14 persons were identified as having had a high-risk exposure to Ebola while working in and around an Ebola treatment center in West Africa that reported unsafe infection control practices. Upon their return to the United States, their exposure risk assessments were completed by SHDs, who made the request for PHTR for those persons with HREs. Foreign MOHs or CDC assessed these HREs, and 16 persons were identified as having had high-risk exposures to Lassa fever and persons exposed during an international outbreak of infection with MERS-CoV. In May 2015, a person who had traveled from West Africa was confirmed to have Lassa fever, and 16 persons were identified as being high-risk contacts: 6 (37%) household contacts, 7 (44%) community contacts, and 3 (19%) healthcare providers. These persons were closely monitored by the SHD and removed from PHTR after completing their incubation periods. In July 2015, in response to the MERS-CoV disease outbreak in South Korea, CDC identified 2 contacts with confirmed commercial air travel involving the United States; both contacts were considered community contacts of patients infected with MERS-CoV and were placed on PHTR. One person was identified in a US territory, monitored until completion of the incubation period, and removed from PHTR. The second person was placed under quarantine in South Korea until completing the incubation period, at which time this person was removed from PHTR and able to travel back to the United States.

**Discussion**

CDC recommended controlled movement for persons with HRE to these high-consequence diseases because of the risk for a person becoming symptomatic and exposing others during commercial travel; federal travel restriction tools were used to support recommendations outlined in published movement and monitoring guidance and in the Federal Register (1,3,9). These PHTRs aligned with recommendations of the International Health Regulations 2005 in response to specific public health risks, as well as with the World Health Organization Emergency Committee guidelines regarding travel restrictions for persons with Ebola and contacts (15,16). No person in this cohort attempted commercial air travel while under PHTR, suggesting that the use of federal travel restriction tools might reinforce the need for adhering to public health recommendations.

Federal PHTR reduced the risk for disease transmission among the traveling public even if any of the restricted persons chose not to comply with public health recommendations and had attempted commercial air travel. Most persons with HREs were located in the United States and under direct active monitoring along with community-level movement restrictions imposed by state authorities. All public health actions regarding travel restrictions were coordinated between state/local authorities and CDC.

Federal PHTR provided support and assurance for SHDs, especially during the 2014–2016 Ebola epidemic, when SHDs were monitoring several thousand persons with various risk classifications for symptoms, in addition to those persons with HREs who were placed on PHTR (17). Because most persons in the data cohort were located in the United States, their exposure risk assessments were completed by SHDs, who made the request for PHTR for those persons with HREs. Foreign MOHs or CDC assessed
the risk for persons abroad who were planning to travel. Exposure risk classifications were developed with CDC subject matter experts and aligned with published disease-specific movement and monitoring guidance (2). CDC continues to evaluate travel restriction criteria as it relates to persons with HREs and disease-specific exposure risk classifications and might refine them as needed during future outbreaks.

Consistent communication and strong collaboration with partners was critical for successfully implementing travel restrictions. The nature and volume of persons placed on PHTR in compressed timeframes during the Ebola outbreak was unprecedented and required close collaboration between local, state, federal, and international partners, as well as the travel industry. SHDs or foreign MOHs were responsible for obtaining biographical data for contacts, determining date of exposure and exposure risk level, and then requesting PHTR placement if a contact was placed under controlled movement. SHDs and MOHs worked with CDC to track dates for removal from PHTR on the basis of incubation periods of contacts to ensure PHTR were removed as soon as the incubation period of the person had been completed. CDC worked closely with the US Department of Homeland Security, using standard processes of internal and external approvals (6,18), to promptly implement and remove PHTR for a large number of persons over a short timeframe.

CDC notified all US-based persons of their placement on and removal from PHTRs; notifications to contacts outside the United States were provided to in-country public health officials who then informed the persons. All persons were compliant with public health recommendations for controlled movement, and none contested their travel restrictions. States assisted persons on PHTRs who were housed at locations near a healthcare facility during their incubation periods. US Department of State assistance was made available to those US citizens placed under PHTRs while located overseas.

In addition, CDC worked closely with the airline industry to minimize the burden for those persons who had travel planned during their incubation period and issued formal requests for airline change fee waivers. The established relationship between CDC and the airline industry was critical to the successful waiver of change fees for persons. US-based airlines generally do not have established criteria for denying boarding for ill passengers and follow CDC recommendations for restricting travel of persons as it protects the health of other passengers traveling on their aircraft.

Challenges in implementing and removing PHTRs for this data cohort were related to the large number of urgent requests for PHTRs over short periods during outbreaks. Implementing and removing PHTRs are detailed administrative processes requiring extensive resources to coordinate an all-hours response to a large number of urgent requests for PHTRs. After the Ebola outbreak, CDC trained surge staff in administrative processes for implementing and removing PHTRs as a means to supplement personnel resources during future outbreaks that generate a high volume of urgent requests for PHTRs.

Under the revised criteria for federal PHTRs (3), and in conjunction with disease-specific Monitoring and Movement Guidance, such as that published for Ebola virus and MERS-CoV (1,9), PHTRs are valuable tools for state and local officials, as well as foreign MOHs, during outbreaks of communicable diseases of public health concern. PHTRs reinforce recommended controlled movement of persons with HREs to communicable diseases, even if these persons refuse to comply with public health monitoring and recommendations to postpone commercial travel. PHTRs can enhance global health security by providing a mechanism to mitigate international importation, transmission, and spread of highly communicable diseases during epidemics of high consequence or emerging infectious diseases.

Acknowledgments

We thank the Texas Department of State Health Services, the Ohio Department of Public Health, the New York City Department of Health and Mental Hygiene, and the New Jersey Department of Health for providing assistance in successful implementation of travel restrictions related to the US cases of Ebola and Lassa fever; the Department of Homeland Security for providing assistance and support of public health travel restriction actions; and staff at CDC Houston; Detroit, New York (John F. Kennedy International Airport), and Newark Quarantine Stations; and Margaret Honein, Shalon Irving, David McAdam, David Montgomery, Erika Odom, Teresa Seitz, Julie Sinclair, Kara Tardivel, Faith Washburn, and Stefanie White for providing assistance related to implementation of travel restrictions.

Ms. Vonnahme is an epidemiologist in the Division of Tuberculosis Elimination, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Centers for Disease Control and Prevention, Atlanta, GA. Her primary research interests are infectious diseases, migrant populations, and global emergency response.

EID Adds Advanced Search Features for Articles

Emerging Infectious Diseases now has an advanced search feature that makes it easier to find articles by using keywords, names of authors, and specified date ranges. You can sort and refine search results by manuscript number, volume or issue number, or article type. A quick start guide and expandable help section show you how to optimize your searches.

https://wwwnc.cdc.gov/eid/AdvancedSearch

EID’s new mapping feature allows you to search for articles from specific countries by using a map or table to locate countries. You can refine search results by article type, volume and issue, and date, and bookmark your search results.
