In 2015, a cholera epidemic occurred in Tanzania; most cases and deaths occurred in Dar es Salaam early in the outbreak. We evaluated cholera mortality through passive surveillance, burial permits, and interviews conducted with decedents’ caretakers. Active case finding identified 101 suspected cholera deaths. Routine surveillance had captured only 48 (48%) of all cholera deaths, and burial permit assessments captured the remainder. We interviewed caregivers of 56 decedents to assess cholera management behaviors. Of 51 decedents receiving home care, 5 (10%) used oral rehydration solution after becoming ill. Caregivers reported that 51 (93%) of 55 decedents with known time of death sought care before death; 16 (29%) of 55 delayed seeking care for >6 h. Of the 33 (59%) community decedents, 20 (61%) were said to have been discharged from a health facility before death. Appropriate and early management of cholera cases can reduce the number of cholera deaths.

Cholera is an acute diarrheal illness caused by infection with the bacterium *Vibrio cholerae* (1). Severe cholera can be rapidly fatal; patients who do not receive appropriate treatment could die within hours (1). Prompt replacement of fluids and electrolytes through the use of oral rehydration solution (ORS) and intravenous fluids can prevent cholera death (2). With appropriate care, case-fatality rates for cholera should be <1% (1).

Tanzania reported an outbreak of cholera on August 15, 2015 (3,4). At that time, 6 of 8 countries bordering Tanzania were experiencing cholera outbreaks (5). Cholera outbreaks can spread rapidly, crossing national borders, and are a major global health security problem.

Early in the Tanzania outbreak, most cases and deaths were reported in Dar es Salaam, where 3,371 cases and 36 deaths (case-fatality rate 1.1%) had been recorded by October 31, 2015. Deaths were exclusively reported from cholera treatment centers (CTCs), but additional deaths in the community were rumored. When cholera deaths in the community were suspected, an environmental health officer was required to visit the decedent’s house, prepare a burial permit, obtain a rectal swab for culture, and assist with the disposal of the body. The burial permit included the decedent’s name, suspected cause of death, and date of death. We conducted a cholera mortality evaluation to identify unreported deaths, investigate household cholera management practices, and describe healthcare-seeking behaviors.

The Study
We obtained a list of persons who were suspected to have died of cholera (decedents) from the CTCs and obtained the burial permits from the CTCs, referral hospitals, and municipal offices (for complete description of methods, see online Technical Appendix 1, https://wwwnc.cdc.gov/EID/article/23/13-0529-Techapp1.pdf). The case definition for suspected cholera death was death of a person ≥2 years of age with acute watery diarrhea with or without vomiting with illness onset after August 15, 2015, in Dar es Salaam. A confirmed cholera death was defined as death of a person ≥2 years of age whose stool was positive for *Vibrio cholerae* O1 (6). All suspected and confirmed cholera deaths identified from CTC reports and burial permits were included in the evaluation.

We developed survey instruments with the Open Data Kit software (https://opendatatkit.org/). Written informed

consent to take surveys was obtained, and then trained enumerators completed surveys with caregivers or relatives of the deceased (online Technical Appendix 2, https://wwwnc.cdc.gov/EID/article/23/13/17-0529-Techapp2.pdf). During January 19–23, 2016, these data were collected electronically on Galaxy Tablets (Samsung, Seoul, South Korea).

During August 16, 2015–January 16, 2016, the cholera surveillance system in Dar es Salaam identified 48 cholera deaths, all reported by CTCs. These deaths included persons who died at CTCs and persons who were dead on arrival. The burial permit assessment identified an additional 53 cholera deaths for a total of 101 total deaths (Figure 1); therefore, 52% of the total deaths were not captured by the existing surveillance system.

Cholera cases and deaths peaked in late September, with fewer deaths reported from November through January (Figure 2, panels A, B). The decrease in deaths coincided with a decrease in reported cholera cases. Of 101 decedents, 45 (45%) were not included in the study: for 35 (87.5%), caretakers could not be located; for 3 (7.5%), the caretakers had moved; 2 (5%) were an entire family unit with no respondent to give a survey; and 5 were misclassified (2 were <2 years of age and 3 had negative cultures with clinical signs inconsistent with cholera). Anecdotal reports suggested that many of the decedents for whom family members and caretakers could not be found were migrant workers who lived alone in single rented rooms, and the homes of others were not disclosed because of the stigma associated with cholera and local political pressure not to report.

Caretakers interviewed for this evaluation were family members (73%), landlords and neighbors (21%), employees (4%), and friends (2%) of the 56 decedents. The median age of decedents was 23 (range 2–80) years, and 32 (57%) were men or boys (Table).

Fecal samples from 39 (70%) decedents yielded *V. cholerae*. Laboratory results from 16 (29%) decedents were not available. The location of death was the community or en route to a health facility for 33 (59%) decedents, a health facility for 22 (39%), and an unknown location for 1 (2%) (Table). Of the 51 respondents who reported that decedents received home treatment, 5 (10%) said ORS was consumed. Reasons the decedents did not take ORS at home included not knowing what ORS was (38%) and not thinking that ORS would help (33%). Of 56 decedents, 26 (46%) consumed fluids other than ORS, including water (30%), soft drinks (13%), and porridge (5%), at home before their deaths.

Of 55 decedents with a reported time of death, 44 (80%) died within 24 hours of symptom onset, and of the 51 (93%) decedents who sought care before death, 16 (31%) waited >6 h from symptom onset to seek care. All decedents were able to reach a health facility from their home within 1 hour. Of 33 decedents who died in the community or en route to a health facility, 20 (61%) had previously been discharged alive from a health facility.

**Conclusions**

More than half of the records of cholera deaths in Dar es Salaam were missing from the existing surveillance system, which only captured patients who arrived at CTCs. Deaths that occurred in other treatment locations

**Figure 1.** Study population for cholera mortality evaluation, Dar es Salaam, Tanzania, August 16, 2015–January 16, 2016.

**Figure 2.** Suspected and confirmed cholera cases (A) and deaths (B) from cholera mortality evaluation and burial permit assessment, by week, Dar es Salaam, Tanzania, August 16, 2015–January 16, 2016. CTC deaths are deaths in patients >2 years of age with suspected or confirmed cholera who died following admission to a hospital or CTC. Community deaths were deaths in persons >2 years of age highly suspected of having cholera or having culture-confirmed cholera who died in the community or en route to a CTC. The date of death could not be determined for 6 decedents who were therefore excluded from the epidemic curves. CTC, cholera treatment center.
to reach a health facility within 1 hour. The failure to seek
timely care was probably a matter of inadequate messaging
to the public.

More than 60% of community decedents were re-
portedly discharged from a health facility before dying,
suggesting inadequate management by health workers or
premature discharge. The Tanzanian Ministry of Health
initiated healthcare provider training in November 2015
to address cholera case management problems; starting
around that time, cholera deaths became infrequent (Figure
2, panel B). The use of rectal swabs to confirm cholera in
decedents might be a useful practice especially in the con-
text of unexplained deaths during cholera outbreaks.

Enhanced surveillance, cholera case management
training, and robust community education focused on de-
tigmatizing the disease, as well as encouraging persons on
the margins of society to seek medical attention for choler-
like symptoms, are needed to manage cholera epidemics.
These practices can help expedite outbreak detection and
response, facilitate the control of cholera at its source, and
prevent deaths, enhancing global health security.

Acknowledgments

We thank the district and regional health management teams in
Ilala, Kinondoni, and Temeke Districts and the environmental
health officers, without whom this study would not have been
possible. We also thank the National Task Force of Tanzania
for input and support throughout the evaluation. Staff of the
Field Epidemiology and Laboratory Training Program deserves
special appreciation for helping gather data for the burial permit
assessment and assisting in navigating institutional review board
approval procedures. We also thank the staff of PSI Tanzania for
assisting in data collection.

Funding for this investigation was provided by the Global
Health Security Agenda of the US Centers for Disease Control
and Prevention.

Dr. McCrickard is an Epidemic Intelligence Service Officer
for the Waterborne Disease Prevention Branch, Division of
Foodborne, Waterborne, and Environmental Diseases, National
Center for Emerging and Zoonotic Infectious Diseases, Centers
for Disease Control and Prevention, Atlanta, Georgia, USA,
where she has worked on cholera preparedness and response
activities in Sierra Leone, Tanzania, and Ethiopia. Her primary
research interests include applied public health research
and epidemiology.

or in the community were not reported. Underreport-
ing of deaths during cholera epidemics, a phenomenon
not unique to Tanzania (5,7,8), poses a threat to global
health security.

We identified 3 anecdotal barriers to reporting cholera
deaths. One barrier was political pressure; because of
the electoral campaign ongoing during the epidemic, health-
care workers might have been discouraged from reporting
cholera cases (9,10). Similarly, in 2008, underreporting
of cholera deaths was observed during an electoral cam-
paign in Kenya (8). Another barrier was influence from lo-
cal leaders; because of the stigma associated with cholera,
these leaders might have wished to deny the presence of
the disease in their communities and created an environ-
ment discouraging others from reporting (11,12). The third
barrier was lack of communication with immigrants; some
decedents reported to be migrant workers who lived alone
did not have social contacts who could serve as caregivers
or report the decedent’s cause of death. Similar observa-
tions have been described in another cholera mortality in-
vestigation (13).

This evaluation suggested that most caregivers of
decedents lacked knowledge of ORS. Other studies have
observed that the use and knowledge of ORS (7,8,14) has
plateaued or declined in countries of sub-Saharan Africa
and Asia since the 1990s (15,16). This decline or plateau
was associated with decreased funding for diarrhea control
projects, declining commercialization of ORS, and inco-
sistent messaging regarding homemade ORS (16). In addi-
tion, >30% of cholera decedents delayed seeking care by
>6 h. Although other cholera mortality studies have not di-
rectly addressed the effect of delays in seeking care, several
studies have identified distance to health facilities or lack of
transportation as barriers to timely care in rural populations
(14,17,18). In this urban epidemic, all decedents were able
