This case illustrates the need to better define the geographic extent and modes of transmission of this debilitating disease so that primary control measures can be identified. In addition, health workers must be provided with the training and tools to diagnose and treat *M. ulcerans*. Research into a point-of-care diagnostic test is needed so that timely treatment can minimize disability and costs to the family.

Acknowledgments

Thanks to Emily Duecke, Sidy Ba, Carlos Bleck, and Teunella Wolters for their sharp clinical skills and therapeutic efforts on behalf of this patient.

About the Author

Ms. Turner is a family nurse practitioner living and working in Dakar, Senegal. Her background includes trauma and pediatric primary care in high-income and low-income countries.

Management of Patients with *Candida auris* Fungemia at Community Hospital, Brooklyn, New York, USA, 2016–2018

Jenny YeiSol Park,2 Nicole Bradley,3 Steven Brooks, Sibte Burney, Chanie Wassner

DOI: https://doi.org/10.3201/eid2503.180927

*Candida auris* is an emerging fungus that can cause invasive infections. It is associated with high mortality rates and resistance to multiple classes of antifungal drugs and is difficult to identify with standard laboratory methods. We describe the management and outcomes of 9 patients with *C. auris* fungemia in Brooklyn, New York, USA.

*Candida auris* is an emerging fungus that can cause invasive infections associated with high mortality rates and is often resistant to multiple classes of antifungal drugs. Risk factors for infection include nursing home exposure; invasive devices, such as tracheostomy tubes or percutaneous endoscopic gastrostomy tubes; immunocompromised status; and use of broad-spectrum antimicrobial drugs (1). On the basis of limited data available, echinocandins are recommended as initial therapy for *C. auris* infection (2). We review the management of 9 case-patients who had *C. auris* fungemia at a 300-bed community hospital, attached to a 450-bed nursing home, in Brooklyn, NY, USA. There have been 9 occurrences of *C. auris* fungemia at this institution since 2016.

Our case series demonstrates the complex patient population at risk for invasive infection with *C. auris*. Patients infected were generally >70 years of age and had multiple chronic concurrent conditions (Appendix Table, https://wwwnc.cdc.gov/EID/article/25/3/18-0927-App1.pdf). Most patients came from nursing homes, and more than half had invasive devices, such as tracheostomies or
percutaneous endoscopic gastrostomy tubes, placing them at high risk for infection at baseline.

In addition, each patient had a recent history of broad-spectrum antimicrobial drug use; many had concomitant resistant organisms isolated and received concomitant antimicrobial drug therapy during their C. auris treatment course. The most common antimicrobial drugs used were meropenem, polymyxin B, and vancomycin. Common bacteria isolated were Acinetobacter sp., Pseudomonas aeruginosa, and Klebsiella pneumoniae. Four patients were admitted to the medical intensive care unit before development of candidemia.

The time from hospitalization to initial infection with C. auris varied among the patients. Approximately 60% of the patients came to the hospital with positive blood cultures on day 1, and fungemia developed in the remaining patients after prolonged hospitalization. Most patients had documented clearance of their blood cultures within 3–5 days of initial isolation. However, 1 patient had a second episode of C. auris fungemia several weeks after he was initially given treatment and documented to have clearance of blood cultures.

All patients were given micafungin as first-line therapy for an average duration of 22 days. The most common dose used was 100 mg/day of intravenous micafungin. Two of the 9 patients required liposomal amphotericin B after failing to respond to micafungin therapy. Both of these patients remained febrile while receiving micafungin monotherapy; 1 was the patient with 2 episodes of C. auris fungemia. The average duration of amphotericin B was 19 days. The in-hospital mortality rate was 22%. Of the 7 patients who were discharged, 43% were discharged after prolonged hospitalization. Most patients had documented clearance of blood cultures within 3–5 days of initial isolation. However, 1 patient had a second episode of C. auris fungemia several weeks after he was initially given treatment and documented to have clearance of blood cultures.

All isolates were markedly resistant to fluconazole, and ≈40% were resistant to liposomal amphotericin B (Appendix Figure). This second finding is of particular concern because liposomal amphotericin B is the recommended second-line agent for management of C. auris in the setting of micafungin failure. On the basis of the resistance patterns at this hospital, patients who failed monotherapy with micafungin had liposomal amphotericin B added rather than switching therapy completely.

We encourage clinicians treating C. auris infections to consider combination therapy with micafungin plus liposomal amphotericin B in patients who fail monotherapy with micafungin. Laboratory limitations mean that timely identification and susceptibility testing of C. auris might not always be possible, and clinicians might often have to defer to local or national epidemiology trends to make the most up-to-date decisions. It is essential to notify the department of health of new cases of infection with C. auris as soon as possible and to educate healthcare personnel to help minimize spread. Clinicians should focus on identifying and minimizing risk factors for acquisition of C. auris and prevention of spread through enhanced infection control procedures.

About the Author
At the time of this study, Dr. Park was a pharmacy resident in the Department of Pharmacy, Kingsbrook Jewish Medical Center, Brooklyn, NY. She is currently an infectious disease resident at the State University of New York Downstate Medical Center, Brooklyn, NY. Her primary research interest is assessing the appropriate use of antimicrobial drugs and associated long-term outcomes.
