

Yaws Disease Caused by *Treponema pallidum* subspecies *pertenue* in Wild Chimpanzee, Guinea, 2019

Appendix

Molecular and Bioinformatics Analyses

We extracted DNA from 2 chimpanzee facial lesion biopsies using the DNeasy blood and tissue extraction kit (QIAGEN, <https://www.qiagen.com>) following the manufacturer's protocol. We screened samples with a quantitative PCR targeting the *polA* gene of *Treponema pallidum*, as described previously (1); both samples were positive. We converted DNA extracts into dual indexed Illumina libraries using the NEBNext Ultra II DNA Library Prep kit (New England Biolabs, <https://www.neb.com>). We enriched the libraries for TPE through in-solution hybridization capture, as previously described (2; B. Mubemba et al., unpub. data, <https://doi.org/10.1101/848382>) sequenced on an Illumina NextSeq (v2 chemistry, 2x150 cycles; <https://www.illumina.com>). We quality-filtered the reads using Trimmomatic v0.38 (removing leading and trailing reads <Q30; clipping reads where average base quality across 4 bp was <30; removing surviving reads <30 nt long) (3). We merged surviving read pairs with Clip and Merge v1.7.8 (<https://anaconda.org/bioconda/clipandmerge>). We combined merged reads and surviving singletons and mapped them to TPE Fribourg-Blanc (RefSeq ID NC_021179.1) using BWA-MEM with a minimum seed length of 29. We sorted mapped reads using Picard's SortSam, de-duplicated them with Picard's MarkDuplicates (<https://broadinstitute.github.io/picard/index.html>), and removed alignments with MAPQ <30 and a mapping length <30 nt using SAMtools (4). Finally, we merged all mapped reads of individual library samples to produce single TPE draft genome. We used Geneious v.11 to call a consensus genome requiring a minimum of 3 unique reads to cover a position for it to be called and applying a majority consensus rule (5).

We performed whole genome alignment using the multiple sequence alignment program MAFFT (6). We then removed all putative recombinant genes (2) and selected conserved blocks using the Gblocks tool (7) in SeaView v4 (8). We performed Bayesian Markov chain Monte Carlo phylogenomic analysis in BEAST (version 1.10.4; <https://www.mybiosoftware.com>) on the resulting alignment of 4,213 variable positions (after stripping off of all ambiguities and identical sites in the final dataset); settings of the analysis were a strict clock model and a coalescent process assuming constant population size. We examined the output of multiple chains of 10,000,000 generations for convergence and appropriate sampling of the posterior using Tracer (version 1.7.1) (9) before merging tree files using Log Combiner (version 1.10.4) (10). We picked the best representative tree from the posterior set of trees and annotated it with Tree Annotator (version 1.10.4: distributed with BEAST). We further edited the resultant maximum clade credibility (MCC) tree file using iTOL (<https://itol.embl.de>) (11). *T. pallidum* sequences used in this study are listed in the Appendix Table (12–24).
