The infectivity of severe acute respiratory syndrome coronavirus 2 in deceased persons and organisms remains unclear. We studied transgenic K18-hACE2 mice to determine the kinetics of virus infectivity after host death. Five days after death, virus infectivity in the lung declined by >96% and RNA copies declined by 48.2%.

The safe handling and disposal of bodies of persons who have died of coronavirus disease (COVID-19) is vital for infection control. Although cremation or burial practices are mainly dictated by religious and societal customs, deaths associated with contagious illness warrant appropriate precautions. Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the causative agent of COVID-19, is rapidly inactivated (>2 log10) within hours on nonporous surfaces (1). In addition, several studies have detected viral RNA by reverse transcription PCR (RT-PCR) of nasopharyngeal and pharyngeal mucosal swab specimens, skin swab specimens, and tissue samples collected during autopsies at different times after death (2–5). Furthermore, infectious virus was isolated in 2 of 4 cases at 4–17 days postmortem; however, this study did not quantify virus titers to determine the loss of virus infectivity (6). A separate study found that infectious virus was undetectable after exhumation at 3–4 months postmortem (7). Overall, RNA detection by RT-PCR might not directly correlate with virus infectivity or duration of symptomatic disease.

Transgenic K18-hACE2 mice provide a surrogate model to study the kinetics of SARS-CoV-2 viral replication during infection (8) and after host death. In humans and K18-hACE2 mice, little evidence exists for extrapulmonary dissemination of SARS-CoV-2, except for neurotropism in younger mice, a finding that has not been demonstrated reliably in humans. We investigated the temporal decay of infectious SARS-CoV-2 in postmortem tissues of infected K18-hACE2 mice. All experimental procedures were conducted in accordance with the standards and approved by the Committee on the Use of Live Animals in Teaching and Research (approval no. 5511-20) at The University of Hong Kong (Hong Kong, China).

We infected twelve 14–20-week-old mice with 1 × 10^4 50% tissue culture infectious dose (TCID_{50})/25μL SARS-CoV-2 by the intranasal route. Five days later, after the mice had lost 18.8% (SD 7.77%) of their body weight, we euthanized them by ketamine/xylazil anesthesia. We wrapped each carcass in a sealable plastic bag, similar to the storage of human corpses, and stored them intact at 4°C, which is standard mortuary temperature. On days 0, 1, 5, and 14 after death, we dissected 3 carcasses and tested the lung tissue for coronavirus nucleoprotein (N) by histologic and immunohistochemistry assays (9) (Appendix Figure, panels A–H, https://wwwnc.cdc.gov/EID/article/27/12/21-1612-App1.pdf). We quantified infectious virus by culture (Figure, panel A) and viral RNA by RT-PCR (Figure, panel B) (Appendix).
Viral decay, measured using TCID$_{50}$ for infectious virus and RNA copies of the N gene detected by RT-PCR, occurred over a 14-day period (Table). At day 1 we observed a 50% reduction of infectious virus and 48.8% loss of viral RNA (Figure, panels A, B). By day 5, levels of infectious virus had fallen by 96.5%, whereas viral RNA remained at 48.2% compared with day 0 (Figure, panels C, D). At day 14 only 0.7% of the initial infectious virus and 17% of viral RNA remained. Plenzig et al. (7) detected viral RNA in 2 exhumed corpses at 3 months postmortem, despite an absence of infectious virus. We used hematoxylin and eosin staining to detect viral nucleoprotein in lung tissue. We observed persistent antigen staining until day 5; by day 14, only 1 of 3 samples had detectable staining (Appendix Figure).

We euthanized the mice 5 days after infection, when the lungs had a high viral load. However, COVID-19 deaths usually occur during later stages of disease, by which time infectious viral load has decreased from the peak usually seen early during the symptomatic phase of the illness (10). We detected virus antigen in the lungs of all mice at 5 days postmortem; infectious virus had declined by 96.48%, but viral RNA declined by only 48.21%. Our results show that infectious virus declines earlier than viral RNA or antigen in postmortem tissues.

These findings have implications for the safe handling of deceased COVID-19 patients. Infectious virus can persist on inanimate surfaces for up to 14 days at lower temperatures (<4°C), but rapidly decays in postmortem tissue samples. We observed a 96.5% decrease in infectious virus by day 5 and a 99.3% decrease by day 14. Most published postmortem studies in humans have reported viral load at the time of death using cycle threshold values rather than N gene copies as we have done; results range from 17–36 for cycle threshold values and 0–5.49 log$_{10}$ for N gene copies (11). Therefore, the maximum potential risk of transmission from an infected...
Corpse is during the first 24 hours after death. By day 5, the amount of infectious virus has decreased by 96.48%. If proper biosafety precautions and personal protective equipment are used to handle the corpse during autopsy or preparation for burial or cremation, we believe that the burial or cremation process is unlikely to spread disease.

This study was partly supported by the Health and Medical Research Fund (grant no. HMRF COVID-190115 to M.P. and S.A.V.), and Commissioned Research on Control of Infectious Diseases (phase III and IV) from the Health and Medical Research Fund (M.P.).

About the Author
Dr. Valkenburg is a viral immunologist at the HKU-Pasteur Research Pole, University of Hong Kong, Hong Kong, China. Her research interests include immune correlates for influenza and severe acute respiratory syndrome coronavirus 2.

We conducted a multi-institutional study in Taiwan and a systematic review of the literature for reports of Guillain-Barré syndrome after coronavirus disease vaccination. This condition, mostly the classic form and the acute inflammatory demyelinating polyneuropathy subtype, has been reported in 39 cases and has occurred within 2 weeks of vaccine administration.

Guillain-Barré syndrome (GBS), an immune-mediated polyradiculoneuropathy with a ≈5% mortality rate, has an incidence worldwide of 0.81–1.91 cases/100,000 person-years (1). GBS has been

Postmortem Stability of SARS-CoV-2 in Mouse Lung Tissue

Appendix

Appendix Methods

Mouse Infection

Twelve 14–20-week-old female K18 mice expressing human angiotensin converting enzyme 2 (hACE2) (The Jackson Laboratory, https://www.jax.org) were infected at the same time with $1 \times 10^4$ TCID$_{50}$/25uL of SARS-CoV-2 ($\beta$CoV/Hong Kong/VM20001061/2020, GenBank accession no. MT547814.1) by the intranasal route. They were culled at day 5 post infection by ketamine/xylazil anesthesia.

Viral Titers

Lung viral titers were determined from homogenates by standard TCID$_{50}$ assay on VeroE6 cells, and viral titers were calculated by the Reed-Muench method as previously described (1). Specimens from lung homogenate supernatant were extracted using QIAamp Viral RNA kit (QIAGEN, https://www.qiagen.com) according to the manufacturer’s instructions, and tested by a quantitative reverse transcription PCR selective for the N gene of SARS-CoV-2 previously published (2) with absolute copy number quantification. A cloned plasmid DNA extract carrying a DNA insert of the N gene was prepared and quantified for DNA copy number. The copy number control plasmid DNA with serial dilutions were included in each PCR run to construct a standard curve to correlate cycle threshold values and gene copy number of samples. Absolute N gene copies in each reaction was deduced. Virus gene copy number per mL was calculated by adjusting dilution effect by nucleic acid extraction.

Immunohistochemistry and N Antigen Staining

Lung tissues were washed in PBS and fixed at the time of collection in 10% neutral buffered formalin. They were processed for hematoxylin and eosin staining and for immunohistochemistry for SARS-CoV nucleoprotein using a rabbit polyclonal antibody (cat no.
40143-T62; Sinobiological, https://www.sinobiological.com) against SARS-CoV nucleoprotein using 1/500 dilution at room temperature for 75 min. Antigen retrieval was performed using microwave in citrate buffer (pH 6.0) for 15 min. Lung inflammation was scored according to Hovart et al. (3) up to a total score of 16 for inflammation in the airway (score of 0–4), vasculature (0–4), and parenchyma (score 0–5), and a separate determination of the amount of N antigen (score 0–5).
