Crimean-Congo hemorrhagic fever (CCHF), caused by Crimean-Congo hemorrhagic fever virus (CCHFV) (1), is a widely distributed arboviral disease. Human CCHF cases have been reported in >30 countries in Africa, the Middle East, Asia, and southeastern Europe (2). However, clinical cases or seroprevalence studies for CCHFV have not been reported in Myanmar, likely because active surveillance in humans or animals has not been established (3).

Hyalomma ticks, 1 of several CCHFV tick family hosts, are considered the primary vector transmitting CCHFV to humans (4). Hyalomma tick distribution extends into Myanmar (5), and CCHF has been reported in the neighboring countries of China and India (6,7). Expansion of CCHF from countries with known virus circulation to neighboring countries could occur through introduction of infected ticks, human CCHF cases, or movement of animals (8). Climate change also is expected to influence the distribution of Hyalomma ticks and CCHFV infections (9), increasing the likelihood of disease expansion.

Human CCHFV infections can occur through contact with an infected tick or with blood or tissues from infected humans or animals. People living or working closely with livestock or who have heavy exposure to ticks are at increased risk for CCHFV infection (10,11). Limited investigations have been performed to identify human exposure to CCHFV caused by wild animal contact, despite serologic evidence for exposure to CCHFV in numerous vertebrate species, including birds (Galiformes and Passeriformes), wild hoof stock (Artiodactyla, Cetartiodactyla, and Perissodactyla), carnivores (Carnivora), bats (Chiroptera), hedgehogs (Erinaceomorpha), rabbits and hares (Lagomorpha), elephants (Proboscidea), rodents (Rodentia), and turtles (Testudinata) (12).

CCHF has been designated by the World Health Organization as 1 of 10 high-priority emerging infectious diseases (https://www.who.int/emergencies/diseases/2018prioritization-report.pdf). The designation was based on CCHF’s epidemic and emergence potential, a high case-fatality rate of up to 80% depending on healthcare infrastructure and CCHFV genotype, and a lack of approved medical countermeasures for CCHF (14). Most initial reports of CCHF cases in individual countries have been preceded by epidemiologic surveys that provided evidence of local CCHFV circulation. Our goal was to conduct

Seroepidemiologic Survey of Crimean-Congo Hemorrhagic Fever Virus in Logging Communities, Myanmar

targeted CCHFV surveillance of Myanmar logging communities, which contain an occupational group with expected high exposure to ticks, domestic livestock, and wild animals.

The Study

Myanmar uses a traditional method of elephant logging for timber harvest. Consequently, Myanmar has a large network of communities in which loggers live together in temporary villages with their families and occasionally migrant laborers. We collected data from 102 healthy persons from 5 elephant logging communities in and near the Yenwe Forest Reserve, a protected area in central Myanmar, during June 2016–August 2018. Most (57/102) participants, including persons from forest management, logging crews, and elephant caretakers, worked in the protected area and were exposed to forested areas and vectors associated with CCHFV (Table 1). Participants were 17–67 years of age and the median age was 32.5 years. We collected venous blood samples and quantitative medical and behavioral questionnaires from each participant (Appendix, https://wwwnc.cdc.gov/EID/article/27/6/20-3223-App1.pdf).

We used a bead-based MagPix (Luminex Corporation, https://www.luminexcorp.com) assay platform, developed at the US Army Medical Research Institute of Infectious Diseases, to detect specific IgG reactivity against the nucleoprotein of CCHFV. We used molecular detection of conserved regions of the small, medium, and large segments of bunyavirus to detect CCHFV viremia with conventional PCR (Appendix).

We identified previous CCHFV exposure among study participants, but we did not detect any active infections. Study participants did not exhibit any signs of hemorrhagic fever, and none reported having previously suffered symptoms of hemorrhagic-like illnesses. All participants tested negative for bunyaviruses by consensus PCR. Among study participants, 9.8% (10/102) were seropositive for CCHFV by MagPix IgG assay. Samples categorized as positive ranged from 1,124–8,911 mean fold increase (MFI) and a signal-to-noise ratio (S/N) of 33.8–207.8. Negative samples had an MFI of 44–854 and 1–19.9 S/N. Persons 31–40 years of age were significantly more likely to be seropositive for CCHFV (p = 0.05) compared with other age groups. We noted no statistically significant associations between specific occupations and CCHFV exposure (Table 1).

Persons who reported handling live or recently slaughtered primates (age-adjusted odds ratio $OR_{age\ adjusted} = 5.53; p = 0.020$) or wild carnivores ($OR_{age\ adjusted} = 1.3; p = 0.004$) in their lifetimes were more likely to have been exposed to CCHFV (Table 2). Handling primates was significantly correlated with handling carnivores (Pearson’s correlation = 0.6; p<0.001). Therefore, we used independent multivariable logistic regression models to adjust for age while assessing the association of CCHFV seropositivity for these 2 factors. More male than female persons reported

handling primates (20 male vs. 3 female persons) and carnivores (9 male vs. 3 female persons) and their ages ranged from 19–60 years. Handling primates or carnivores (9 male vs. 3 female persons) and their exposure to CCHFV in this community. We evaluated occupations associated with increased forest contact, and thus tick habitat, such as resource extraction, protected area worker (forest ranger), or hunter, as a combined variable, but we found no statistically significant association between occupation and CCHFV exposure.

Contact with domestic animals also was not the likely route of CCHFV exposure in this community. Study participants were not frequently exposed to ruminants, the domestic animal group most reported as associated with CCHFV exposure in endemic countries. Participants were more likely to report contact with pigs or poultry, but these animals have not been identified as amplifying hosts for CCHFV. Contact with live or dead domestic animals of any kind was not associated with CCHFV exposure (Table 2).

Nonhuman primates have not been implicated as natural reservoir hosts or sources of human CCHFV infection. However, rhesus macaques (Macaca mulatta) and long-tailed macaques (M. fascicularis), which

range throughout Myanmar, have been infected with CCHFV in laboratory settings. Rhesus macaques develop viremia without clinical signs, but long-tailed macaques develop signs of clinical illness and viremia similar to disease progression in humans (15). Contact with blood or other bodily fluids, including saliva, urine, or feces, during a period of viremia in macaques could lead to human infection. Similarly, wild carnivores have not been implicated as natural reservoir hosts for CCHFV, but red foxes (Vulpes vulpes), which are thought to range in Myanmar, and Pallas’s cats (Otocolobus manul), which range in central Asia, have demonstrated CCHFV seropositivity and could serve as sources of human infection, particularly through bushmeat hunting, which exposes persons to animal blood and body fluids.

**Conclusions**

Our findings indicate that CCHFV is circulating in Myanmar with human infections that are either mildly symptomatic or occurring in populations that fall outside of existing surveillance systems. Although exposure to domestic animal amplifying hosts is the most commonly reported exposure type for human CCHFV infections in endemic countries, our findings show that persons with close contact with wild animal reservoir hosts, especially blood and body fluids of nonhuman primates and carnivores, also are at risk for CCHFV infection. Surveillance of at-risk populations in Myanmar should be expanded to better prepare for potential future outbreaks of CCHF.

Seroepidemiologic Survey of Crimean-Congo Hemorrhagic Fever Virus in Logging Communities, Myanmar

Appendix

Project Approvals

Study protocols were reviewed independently and ethical approval was provided by the Institutional Review Board (approval no. 889159–2) and Institutional Animal Care and Use Committee (approval no. 19520) at the University of California, Davis, the Ethics Review Committee of the Department of Medical Research (approval no. 012816), the Forest Department of the Ministry of Natural Resources and Environmental Conservation, the Livestock Breeding and Veterinary Department and the Myanmar Timber Enterprise.

Bead-Based Serologic Assay

Specific immunoglobulin G (IgG) reactivity against Crimean-Congo hemorrhagic fever virus (CCHFV) was detected by using a bead-based assay, MagPix (Luminex Corporation, https://www.luminexcorp.com), developed at the U.S. Army Medical Research Institute of Infectious Diseases. MagPix has demonstrated an enhanced sensitivity profile relative to conventional ELISA (1,2) and detailed methods have been described previously by Smith et al. (3). In brief, recombinant CCHFV nucleoprotein, produced in a baculovirus expression system and based on the IbAr10200 isolate (GenBank accession no. KY484036) as a reference strain, were conjugated to magnetic microspheres by using the xMAP Antibody Coupling Reagent Kit (Luminex Corporation) according to the manufacturer’s instructions. Antigen coupled beads were combined with 1:100 diluted serum and analyzed on the MagPix instrument. Data were evaluated as signal to noise (S/N), with noise being the average median fluorescence intensity of each bead set in response to naive serum samples. We considered any sample with S/N >20 to be seropositive.
Assay Validation

In a comparative study evaluating the immune response to both CCHFV strain Kosova Hoti (GenBank accession nos. DQ133507, EU037902, EU044832) and strain Afg09–2990 (GenBank accession nos. HM452307, HM452306, HM452305) in experimentally infected Cynomolgus macaques (*Macaca fascicularis*), host antibody response was measured from 1–28 days post CCHFV inoculation by viruses derived from both IgG MagPix assay and neutralization assay. Virus-neutralization response was evaluated by using a virus-like particle (VLP) system with glycoproteins based on CCHFV strain IbAr 10200. We observed the emergence of neutralizing antibodies in serum samples by day 9 post infection for both groups, with broadly similar kinetics and endpoint titers between the Hoti and Afg09 infected groups. Mean fold increase (MFI) values averaging 5,737 corresponded with an 80% plaque reduction neutralization titer (PRNT$_{80}$) of 1:100 and MFI values averaging 10,243 corresponded with a PRNT$_{80}$ of 1:400. MagPix and PRNT$_{80}$ values both peaked at day 21 post inoculation.

Determination of Cutoff Value

To determine cutoff values, MFI and S/N were evaluated for a large multiregional serum set, 1,614 samples from Africa and 634 from Asia. Cutoff’s were conservatively set at S/N of 20, far exceeding standard serologic assay cutoff algorithms that would have used 3 standard deviations above the mean of the negative controls.

PCR Assay for Bunyaviral Small, Medium, and Large Segments

Samples were processed for viral detection by using consensus PCR, which enables the universal amplification of sequences from viruses within a given family or genus, and the subsequent discernment of viral strains within. Total nucleic acid was extracted from whole blood by using Direct-zol RNA Miniprep Kits (Zymo Research, https://www.zymoresearch.com) according to the manufacturer’s instructions. Total RNA was reverse transcribed into complementary DNA (cDNA) by using SuperScript III (Invitrogen, https://www.thermofisher.com) according to the manufacturer’s instructions, and 3 assays were used for detection of bunyaviral small, medium, and large segments as described previously by Briese, et al. (4).
**Statistical Analyses**

To evaluate associations between human demographic and animal contact behaviors, all demographic factors, including age, sex, and livelihood, were first evaluated for associations with animal contact behaviors to assess potential confounding. Fisher exact tests were used to determine associations between CCHFV exposure and demographic as well as high-risk human–animal contact behaviors. Odds ratios were calculated by using a conditional maximum likelihood estimate method. For variables, in which 0-count cells were present, we calculated odds ratios by using an unconditional maximum likelihood estimate, Haldane-Anscombe correction. We considered $p<0.05$ statistically significant. Then we used multivariable logistic regression to assess the association between high-risk wild animal contact behaviors and other risk factors that were significant on bivariate analysis. Variables were included when they significantly improved model fit, based on the likelihood ratio test ($p<0.1$), while minimizing the Akaike information criterion. Overall model fit was assessed by using the Hosmer-Lemeshow goodness-of-fit test. All statistical analyses were performed using R version 3.6.1 (R Foundation for Statistical Computing, https://www.r-project.org).

50. Which crops are at this site? Select all that apply.
- coffee, tea, or cocoa plants
- fruit or nut trees
- oil tree plantation
- oil seed crops
- hardwood plantation
- dry grains
- sugar
- vegetable or fruit crops
- pulses/legume
- fiber
- forages
- cover crops
- fallow fields
- rubber
- fruits or nuts

51. How long have the crops / plantations been growing here?
- Less than 1 y
- 1–2 y
- 2–5 y
- 5–10 y
- 11–20 y
- 21–30 y
- Greater than 30 y

52. How frequently are crops / plantations harvested?
- Less than 1 y
- 1–2 y
- 2–5 y
- 5–10 y
- 11–20 y
- 21–30 y

53. What wild animals live in crops / plantations?
- rodents/shrews
- bats
- non-human primates
- birds
- carnivores
- ungulates
- pangolins

54. What type of work or industry is conducted here? Select one option.
- underground mining (by shafts or tunnels)
- open surface mining
- hydraulic mining (high pressure water)
- gathering, panning, or collecting
- oil well/gas field
- logging
- other

55. What product(s) are extracted? Select one option.
- coal
- coltan
- diamond or other gemstone
- tin
- gold/silver
- lead
- oil/gas
- timber/plant
- electricity
- other (please specify)
56. Do you live on the work site?  yes  
   no
57. To the best of your knowledge, how many people work at this site?  
   <10  
   10–100  
   101–1000  
   1001–10,000  
   >10,000
58. How long have you worked at this site?  
   <1 mo  
   1 mo–1 y  
   >1 y–5 y  
   >5 y
59. Is there on-site food production?  yes  
   no
60. If yes, who pays for the cost of growing the food crops?  the company  
   the workers
61. Is there meat available for consumption?  yes  
   no
62. If yes, where does the meat come from?  
   farmed onsite  
   farmed and purchased from nearby local communities  
   purchased from wholesale market  
   locally caught/hunted  
   bought frozen  
   don't know
63. Is it possible to consume bushmeat/wild animal meat on or near the site?  yes  
   no
64. Is there a designated area for rubbish, including animal waste from slaughter/butcher and animal excrement?  yes  
   no
65. If yes, do people use the designated location for rubbish?  yes  
   no
66. Do any animals raid food supplies or destroy crops?  yes  
   no
67. If yes, what animals?  Select all that apply.  
   rodents/shrews  
   bats  
   non-human primates  
   birds  
   carnivores  
   ungulates  
   pangolins  
   poultry/other fowl  
   goats/sheep  
   camels  
   swine  
   cattle/buffalo  
   dogs  
   cats
68. What is done to stop animals from raiding or destroying food supplies?  Select all that apply.  
   barriers around fields  
   barriers on individual trees  
   fire  
   poison  
   traps  
   shooting  
   loud sounds  
   domestic/guardian animals  
   flooding
## Questions

### 69. What animals have you hunted since this time last year? Select all that apply.
- rodents/shrews
- bats
- non-human primates
- birds
- carnivores
- ungulates
- civets
- pangolins

### 70. Since this time last year, what methods have you used to hunt/trap animals? Select all that apply.
- snare
- bow
- hands
- gun
- machete
- knife
- net
- cage
- trap
- other

### 71. What is the purpose of your trapping or hunting? Select all that apply.
- for consumption at home
- for sale for consumption
- for sale alive at market
- for sale of animal products
- live trapping of nuisance animals
- culling of nuisance animals

### Since this time last year, when you hunt or trap:

#### 72. Are you exposed to blood?
- yes
- no

#### 73. Have you been scratched or bitten?
- yes
- no

#### 74. Since this time last year, have you seen an outbreak of dead wild animals?
- yes
- no

#### 75. If yes, which wild animals? Select all that apply. (add species list)
- rodents/shrews
- bats
- non-human primates
- birds
- carnivores
- ungulates
- pangolins

#### 76. What do you do when you find an animal dead (not in a trap or shot by another hunter)? Select all that apply.
- touch it to see if it is still fresh
- butcher in the forest
- smoke or cook in the forest
- take home to prepare
- bury it
- report it to authorities
- take it to sell it
- nothing
- other

#### 77. How do you transport a dead animal, if you take it? Select all that apply.
- not wrapped
- wrapped in leaves or other natural material
