Antiphospholipid syndrome (APS), first described in 1983 to 1986, is characterized by a wide variety of hemocytopenic and vasculocclusive manifestations and is associated with antibodies directed against negatively charged phospholipids. Features of APS include hemolytic anemia, thrombocytopenia, venous and arterial occlusions, livedo reticularis, pulmonary manifestations, recurrent fetal loss, neurologic manifestations (stroke, transverse myelitis, Guillain-Barré syndrome); and a positive Coombs test, anticardiolipin antibodies, or lupus anticoagulant activity (1). The factor(s) causing production of the antiphospholipid antibodies in primary antiphospholipid syndrome (PAPS) remain unidentified (2).

A substantial number of patients with Mycoplasma pneumoniae–induced respiratory disease have anticardiolipin antibodies (3). Furthermore, many clinical criteria for APS have also been well documented in patients with M. pneumoniae infection, including Guillain-Barré–like illness and other central nervous system manifestations, hemolytic anemia, positive Coombs test, thrombocytopenia, and arthritis (4).

In this report, we describe the case of a patient with clinical features of PAPS and a documented bacteremic infection due to M. penetrans (5).

**Case**

One month before hospital admission, a previously healthy non-HIV-infected 17-year-old woman (blood group O Rh+) who had not previously received a blood transfusion and had not had sexual experience had acute onset of arthritis of both ankles, generalized arthralgias, fever, progressive asthenia, and hemolytic anemia (hemoglobin 87 g/L, unconjugated bilirubin 25.1 µmol/L). In the 30 days before hospital admission she had not received medications other than nonsteroidal antiinflammatory drugs for 5 days. Three days before hospital admission, she became ill with respiratory distress, generalized weakness, anorexia, and inability to walk.

On admission to the hospital (day 1), physical examination showed severe pallor, a swollen cervical lymph node, slight edema of both legs, tachycardia, and no hypertension. Laboratory data showed severe hemolytic anemia (hemoglobin 34 g/L, lactate dehydrogenase 5.1 µmol/s/L), leukocytosis (24.5 x 10^9/L), thrombocytopenia (28.0 x 10^9/L), and normal renal function. A Coombs test was positive at 4°C, 22°C, and 37°C. Blood and bone marrow smears did not show a neoplastic process. The nonsteroidal antiinflammatory drugs were suspended, and treatment was started with a combination of methylprednisolone (1 gm bolus q24h intravenously [i.v.] for 3 days) and trimethoprim/sulfamethoxazole (80/400 mg q12h orally) on day 2, but her condition deteriorated. On day 3, the antibiotic treatment was changed to ceftazidime (1 gm q8h i.v.).
Transfusion was not attempted because serologic tests indicated the lack of compatibility; there was a strong positive mismatch incompatibility in 55 different blood samples and a mild mismatch in one sample. Another transfusion was partially rejected because of unidentified nonspecific antibodies. On day 4 severe respiratory distress and hypoxemia developed, requiring a ventilator, and the patient was admitted to the intensive care unit. Livedo reticularis was noted, and methylprednisolone (125 mg q8h i.v.) was administered. Venereal Disease Research Laboratory tests were negative as were tests for lupus erythematousus. The patient had anti-dsDNA antibodies (Kallestad Quantafluor \textit{Crithidia lucilae} Sanofi Diagnostic Pasteur, Inc.) but positive antcardiolipin antibodies by enzyme-linked immunosorbent assay (ELISA) (100 GPL units) (negative test $< 10$ GPL units) (ImmunoWell, Cardiolipin Antibody Immunoglobulin [Ig]G ELISA; and Reaads Medical Products, Inc.), which remained positive 4 and 12 months later, and antiplatelet antibodies by immunofluorescence (Anti-Human IgG H-chain Fluorescein conjugated, OTY-05 Behring Diagnostics). Laboratory data showed hemoglobin 33 g/L, leukocyte 23.6 x 10\(^9\)/L, a prolonged activated partial thromboplastin time $> 150$ seconds (control $< 42$ seconds) and prothrombin time of 26.1 seconds (control 14.0 seconds), International Normalized Ratios value $= 3.09$, and the presence of lupus anticoagulant (LA) antibodies (prolonged Russell viper venom time and confirmed by the STACLOT LA ELISA test, Reaads Medical Products, Inc.). Respiratory secretions were culture-negative and negative by immunofluorescence for respiratory syncytial virus, adenovirus, influenza A, influenza B, parainfluenza 1,2,3, and \textit{Chlamydia}. Serologic analysis indicated that the patient had no antibodies against HIV, hepatitis B surface and core antigens (HbsAg, Hbc), or hepatitis C virus. No acid-fast bacilli or other bacteria were observed on blood and tracheal aspirate swabs. In addition, thoracic radiography showed only bilateral diffuse pulmonary infiltrates, which was not suggestive of an anaerobic infection.

On day 2 of hospital admission, blood and throat samples were cultured for aerobic flora and mycoplasma. \textit{M. penetrans} in pure culture was isolated from the patient’s blood (isolate HF-1) and throat (isolate HF-3). Later \textit{M. penetrans} was isolated from tracheal aspirate in pure culture (isolate HF-2). Treatment was initiated on day 6 with clindamycin 600 mg q8h i.v. and vancomycin 500 mg q6h i.v. The patient also received transfusion of two units of washed red blood cells.

By the microbroth dilution method (6), the HF-1 isolate was sensitive to clindamycin, clarithromycin, azithromycin, erythromycin, tetracycline, doxycycline, ofloxacin, and chloramphenicol but resistant to vancomycin and gentamicin. After 3 days of treatment, the patient improved clinically and was released from the intensive care unit on day 9; thoracic radiographs were clear.

The unique evidence of thrombosis was a low-degree paresthesia of both legs while the patient was receiving anticoagulant therapy; when the condition developed, anticoagulant therapy was increased. The patient received physiotherapy to correct paresis and reduced sensation in the left foot and ankle region. She left the hospital after 26 days, with minimal evidence of peripheral neuropathy as a sequela.

\textit{M. penetrans} infection was detected in the patient’s specimens prior to culture and was confirmed by specific polymerase chain reaction (PCR) (7) (Figure 1A, 1B). Similar results were obtained by another pair of PCR primers also within the 16S rRNA gene and designed for the specific detection of \textit{M. penetrans} (data not shown).

A. \textit{M. penetrans} PCR genomic amplification with the primers MYCPENET-P and MYCPENET-N (7) and analyzed by electrophoresis in 2% agarose gel. Lysates from the following original samples: throat swab (lane 1); tracheal aspirate (lane 2); blood (lane 3); first blood subculture (HF-1 isolate) (lane 4); \textit{M. penetrans} GTU-54-6A1 (lane 5), showing the amplification product of 407-bp; and negative control (lane 6). B. Southern blotting of the same material. Hybridization with the internal oligonucleotide (MYCPENET-S) probe confirmed the specific amplification of \textit{M. penetrans} genetic sequences.](image-url)
shown). Samples from both original specimens and broth cultures were tested by PCR for other human mycoplasmas (8,9), but none were detected (data not shown).

The sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) protein patterns of different extracts (whole cell lysate, Triton X-114 extracts) for the isolate HF-1 and the type strain GTU-54-6A1 were almost identical (Figure 2A). Upon close examination, minor differences were found, in particular for antigens approximately 38 kDa in both SDS and Triton X-114 extracts. Ultrastructural examination of the HF isolates by transmission electron microscopy showed mycoplasma cells with morphologic features typical of M. penetrans (Figure 2B).

Serologic assays (ELISA and Western blot) with Triton X-114-extracted antigens and other M. penetrans polypeptides from whole-cell lysates both from the type strain GTU-54-6A1 and from our isolate HF-1 were done as previously described (10). A lack of reactivity against the Triton X-114–extracted antigens of M. penetrans was observed by both methods. However, with whole-cell extracts from both type strain and the HF-1 isolate, a 20-kDa polypeptide was immunodetected by Western blotting with three serum samples collected on days 2, 4, and 9 of hospitalization. The 20-kDa polypeptide is an M. penetrans product, but whether the observed reaction corresponds to a cross-reacting epitope is not known. The patient’s samples were also negative for antibodies against M. pneumoniae, M. genitalium, and M. fermentans by ELISA (11) (data not shown).

Conclusions

Since M. penetrans was first reported in 1993 as an emerging infectious agent, M. penetrans–specific antibodies have been detected more frequently (18.2% to 35.4%) in HIV-infected than in non-HIV-infected persons (0.4% to 1.3%) (10). Until this case, M. penetrans had only been isolated eight times (5,10), always from the urine of HIV-infected persons (10).

The results indicating that the isolates HF-1, HF-2, and HF-3 belong to the M. penetrans species are as follows: 1) clinical samples and the mycoplasmal isolates obtained from them were positive in the M. penetrans-specific PCR assay; 2) protein patterns of the HF isolates and the type strain of M. penetrans GTU-54-6A1 were almost identical; 3) serum samples from different patients (10), which contained M. penetrans-specific antibodies on the basis of a reaction with the p35 antigen from the type strain of M. penetrans also reacted with a similar Triton X-114–extracted polypeptide from the HF-1 isolate; and 4) HF isolates exhibited typical morphologic features of M. penetrans, which are unique among mycoplasmas isolated from
humans. The fact that serum from other patients reacted with a similar polypeptide from HF isolates indicates that this protein is produced by this strain of M. penetrans. The lack of M. penetrans strong humoral response in the HF patient was a factor in favor of dissemination of the mycoplasma, hence its isolation from the blood. A possible association between M. penetrans and PAPS should be considered.

Snowden et al. (1990) found antiphospholipid antibodies in more than 50% of patients with M. pneumoniae pneumonia, especially those with severe infections requiring hospitalization (3). Catteau et al. (1995) described two cases of Stevens-Johnson syndrome associated with M. pneumoniae infection and the presence of antiphospholipid antibodies (12). Our patient had manifestations typical of PAPS (2). Thus, this report is the first of M. penetrans isolation in a non-HIV-infected patient and the first of a blood and respiratory tract infection with M. penetrans.
