An outbreak of dengue hemorrhagic fever/dengue shock syndrome (DHF/DSS) occurred in India in 1996. The cause was confirmed as dengue virus type 2, by virus cultivation and indirect immunofluorescence with type-specific monoclonal antibodies. This is the largest such outbreak reported from India, indicating a serious resurgence of dengue virus infection.

Dengue fever occurs worldwide, in nearly all tropical and subtropical countries (1). Dengue virus was first isolated in India in 1945 (2). All four virus types circulate and cause epidemics, but only occasional cases of DHF/DSS have been reported in India (3).

Delhi, situated in the northern part of India, had outbreaks of dengue virus infection due to different dengue virus types in 1967, 1970, 1982, and 1988, but no culture-confirmed cases of DHF/DSS have been reported in India (3).

Delhi had its largest outbreak of DHF/DSS in 1996. The outbreak started the last week of August and continued until the end of November, peaking in mid-October (8,9). A total of 8,900 cases were reported, with a death rate of 4.2% (9). We report results of virologic testing of samples received at the All India Institute of Medical Sciences from patients with suspected dengue fever or denguelike illness from Delhi and its adjoining areas, along with a profile of the culture-confirmed cases.

Virus isolation was carried out on 149 samples received on ice from patients with acute illness. Serum was separated aseptically and stored at -70° C. The standard method of virus cultivation, which used the C6/36 clone of Aedes albopictus cell line, was followed with some modifications (10).

On days 5 and 10, cells were tested by indirect immunofluorescence assay (IFA) by using monoclonal antibodies to dengue virus types 1-4. If IFA was negative for dengue viruses on first passage, a second passage was made, and cells were again harvested on days 5 and 10 for IFA. All four dengue virus types (from the National Institute of Virology, Pune, India) were included as positive controls, and uninfected C6/36 cells were kept as negative controls.

Dengue viruses were isolated in C6/36 cells from 27 (18.1%) of 149 samples processed for virus isolation. Of the 27 isolates, 26 were identified as dengue virus type 2 and one as dengue virus type 1. Sixteen of the 27 isolates were from patients with DHF/DSS, while 11 were isolated from patients with uncomplicated dengue fever. Of the 27 culture-positive patients, 11 (40.7%) were in the 5- to 12-year age group (Table). However, the isolates were nearly equally distributed among children (<12 years) and adults. The ratio of male to female in these 27 cases was 12:15. The median duration of fever at the time of viral isolation was 4 days, on the basis of 24 culture-positive cases for which the duration of fever was available. After 5 days of
Dr. Dar is associate professor in the virology section of the Department of Microbiology at the All India Institute of Medical Sciences, New Delhi, India. His interests include diagnostic virology, viral immunology, and tuberculosis.
