We report the first description, confirmed by bacteriologic and molecular (polymerase chain reaction and pulsed-field gel electrophoresis) analysis, of an infection in animals caused by *Lactococcus lactis* subsp. *lactis*, affecting waterfowl.

Until recently, members of the genus *Lactococcus* were considered opportunistic pathogens (1,2). They are often misidentified as enterococci or streptococci (3,4), and the difficulties in correctly identifying them have probably hindered elucidation of their clinical significance. However, the number of clinical cases associated with infections by these microorganisms has increased in the last decade in both humans and animals (5-7). *Lactococcus lactis* subsp. *lactis*, *L. piscium*, and *L. garvieae* are recognized as the species with clinical significance for human and veterinary medicine (2,8). In humans, *L. garvieae* and *L. lactis* subsp. *lactis* have been associated with endocarditis (9,10) and have also been isolated from clinical samples of blood, skin lesions, and urine (5,7). In veterinary medicine, *L. garvieae* and *L. piscium* are pathogenic for various fish species (8,11,12), and *L. garvieae* causes mastitis in ruminants (13,14). However, infection by *L. lactis* subsp. *lactis* in animals has not previously been reported. We present the first microbiologic and molecular evidence for infection produced by *L. lactis* subsp. *lactis* in waterfowl.

The Study

From September to November 1998, a mass die-off was detected among waterfowl in southwestern Spain, affecting >3,000 birds (0.6% of the total waterfowl population in the area). The species most affected were coots (*Fulica atra*) (26.9%), shovellers (*Anas clypeata*) (25.1%), and mallards (*Anas platyrhynchos*) (13.8%). Overall, 20% of the birds died. Affected birds showed general weakness, evidenced by drooping wings and sluggishness; approximately 50% had respiratory distress. At necropsy, most animals had mild lung congestion; no other lesions were found at postmortem examination.

Samples from the lungs, liver, and spleen of five diseased birds (one mallard, S-15; three shovellers, S-16, S-18, and S-19; and one coot, S-17) were submitted to the Animal Health Department at the School of Veterinary Medicine of Madrid for microbiologic analysis. After 48 hours of incubation at 37°C, pure cultures of weakly α-hemolytic catalase-negative cocci were obtained on blood agar plates from samples of lung (S-15, S-16, and S-17) and liver and spleen (S-15, S-16, S-17, and S-18). All 11 clinical isolates had an identical biochemical profile, which was identified as *L. lactis* subsp. *lactis* by the Rapid ID 32 Strep system (bioMérieux España, S.A., Madrid).

*L. lactis* subsp. *lactis* and *L. garvieae* are the two species more frequently found in human and animal infections (2). Routine clinical microbiologic diagnosis requires accurate discrimination of the two species, as their similar biochemical reaction patterns may lead to misidentification (2,4). Although physiologic tests, differences in antimicrobial susceptibility, whole-cell protein, and DNA or RNA analysis (4,7,13) have been proposed to distinguish them, some of these techniques are not reliable or may be too time-consuming, limiting their use for routine identification. For these reasons, the clinical isolates were also identified by a polymerase chain reaction (PCR) assay, which has been successfully used to identify many other pathogens (15,16).

Specific primers LLF 5'-GCAATTGCATCACTCAAAGA and LLR 5'-ACAGAGAACTTATAGCTCCC were designed from diagnostic regions of the *L. lactis* subsp. *lactis* 16S rRNA gene sequence (accession number M58837). PCR amplifications were performed in a 100-µL reaction volume containing 150 ng each of the two primers, 1 mM each of deoxynucleoside triphosphate, 1 U of Taq DNA polymerase (Biologuais, Inc., Madrid, Spain), and 25 ng of template DNA in 1x reaction buffer. The amplification was carried out in a PTC-100 thermal cycler (MJ Research, Inc., Watertown, MA), under the following conditions: initial denaturation at 94°C for 2 minutes, followed by 30 cycles of denaturation for 1 minute at 92°C, primer annealing for 1.5 minutes at 50°C, primer extension for 2 minutes at 72°C, and a final extension of 5 minutes at 72°C. The following bacterial strains were used to test the specificity of the PCR assay: *L. lactis* subsp. *lactis*, ATCC 19435 and ATTC 11007; *L. garvieae*, NCFB 2155; four clinical isolates of *Lactococcus garvieae* (1336, 1458, 1982, and 4294, isolated from lactococcosis in trout); *L. piscium*, NCFB 2778; *Streptococcus iniae*, ATCC 29187; *Vagococcus fluvialis*, NCFB 2497; and *Enterococcus faecalis*, CECT 481. All the *L. lactis* subsp. *lactis* clinical isolates generated an expected PCR amplification product of 650 bp. No amplification was observed with any other *Lactococcus* species tested, indicating the specificity of the PCR assay (Figure 1). These results confirmed those of the biochemical identification, as well as the utility of this PCR assay for spe-
and sotypes of isolates (Figure 2), which were clearly distinct from the pul-
posable restriction patterns were obtained from all clinical
miologic investigations of lactococci (19,20). Indistinguish-
been successfully applied for strain identification and epide-
isism for waterfowl.

Wild animals, including waterfowl, are known reservoirs for various pathogens (21). We can only speculate about the possibility that waterfowl may be a reservoir for this bacte-
rium. However, wild animal reservoirs for other species of lactococci have been described (22).

Dr. Goyache is associate professor, Facultad de Veterinaria, Universidad Complutense de Madrid. His responsibilities include research and teaching related to clinical microbiology of wildlife and exotic animals.
