Emergence of Ceftriaxone-Resistant Salmonella Isolates and Rapid Spread of Plasmid-Encoded CMY-2–Like Cephalosporinase, Taiwan

Jing-Jou Yan,* Wen-Chien Ko,* Cheng-Hsun Chiu,† Shu-Huei Tsai,* Hsiu-Mei Wu,* and Jiunn-Jong Wu*

Of 384 Salmonella isolates collected from 1997 to 2000 in a university hospital in Taiwan, six ceftriaxone-resistant isolates of Salmonella enterica serovar Typhimurium were found in two patients in 2000. The resistance determinants were on conjugative plasmids that encoded a CMY-2-like cephalosporinase. During the study period, the proportion of CMY-2–like enzyme producers among Escherichia coli increased rapidly from 0.2% in early 1999 to >4.0% in late 2000. Klebsiella pneumoniae isolates producing a CMY-2–like -lactamase did not emerge until 2000. The presence of blaCMY-containing plasmids with an identical restriction pattern from Salmonella, E. coli, and K. pneumoniae isolates was found, which suggests interspecies spread and horizontal transfer of the resistance determinant. Various nosocomial and community-acquired infections were associated with the CMY-2-like enzyme producers. Our study suggests that the spread of plasmid-mediated CMY-2–like β-lactamases is an emerging threat to hospitalized patients and the public in Taiwan.

Bacterial Isolates and Patients

From January 1997 to December 2000, a total of 384 Salmonella isolates from 324 patients were collected at the National Cheng Kung University Hospital, a tertiary-care referral center with 900 beds in southern Taiwan. According to the criteria of the National Committee for Clinical Laboratory Standards (NCCLS) for the disk diffusion method, we selected for further investigation the isolates that exhibited resistance or intermediate resistance to cefpodoxime, ceftazidime, aztreonam, cefotaxime, ceftriaxone, cefoperazone, or cefixime (22). For comparison, 5,520 E. coli isolates and 3,680 K. pneumoniae isolates collected during the same period were included. Of these isolates, 1,210 nonrepetitive E. coli isolates collected from January to September 1999 were investigated previously (23). The 1997 and 1998 isolates were randomly collected and the 1999 and 2000 isolates were consecutively collected. Salmonella isolates were serotyped according to the Kauffman and White scheme (24) by using somatic and flagellar antigens (Becton Dickinson Microbiology, Cockeysville, MD).

We reviewed the medical records of patients infected with or colonized by the organisms being studied. Patients who provided samples positive for the organisms collected from any body site but who had no related signs or symptoms of infection were considered colonized. Nosocomial acquisition of infections in the teaching hospital was defined according to the 1988 definitions from the Centers for Disease Control (25). Patients transferred from other hospitals or nursing homes with infections occurring <48 h after admission were considered to have acquired the infections at the other locations. Hospitalization histories for the previous locations were recorded for outpatients and for inpatients who were colonized by the studied organisms and who provided samples within 48 h after admission.

Susceptibility Testing

The susceptibilities of isolates to antimicrobial agents were determined by using the agar dilution or disk diffusion method.
method according to the NCCLS guidelines (22,26). The antimicrobial agents used for the agar dilution test included amoxicillin, clavulanic acid, ceftriaxone, cefotixin, cef-tazidine, cefotaxime, and imipenem. Sources of antimicrobial agents used in this study are described elsewhere (23). Breakpoints used for susceptibility meet NCCLS criteria; the ceftazidine, cefotaxime, and ceftriaxone breakpoint was 8 µg/mL (26).

**Isoelectric Focusing**

Crude β-lactamase extracts were prepared by using sonication (27) as described previously (23). We performed isoelectric focusing by the method of Matthew et al. (28) with an LKB Multiphor apparatus on prepared PAGplate gels (pH 3.5 to 9.5; Amersham Pharmacia Biotech, Hong Kong, China). Enzyme activities of β-lactamases were detected by overlaying the gel with 0.5 mM nitrocefin in 0.1 M phosphate buffer, pH 7.0. We used TEM-1, TEM-10, SHV-1, SHV-5, CMY-1, CTX-M-3, and CMY-2 β-lactamases as standards (18,23).

**Conjugation Experiments and Plasmid Analysis**

Conjugation experiments were performed by the liquid mating-out assay as described (29) with streptomycin-resistant E. coli C600 as the recipient (30). Transconjugants were selected on tryptic soy agar plates supplemented by 500 µg of streptomycin and 10 µg of ceftazidime per milliliter. Plasmids from transconjugants were extracted by using a rapid alkaline lysis procedure (31). We analyzed restriction fragment length polymorphism of transferred plasmids using agarose gel electrophoresis of plasmid DNA samples treated with the restriction endonuclease EcoRI (Roche Molecular Biochemicals, Mannheim, Germany). The restricted plasmid DNA samples were then transferred to a nylon membrane (Amersham Pharmacia Biotech) and subjected to Southern hybridization. The plasmid sizes of transconjugants were estimated by adding restriction fragments.

**Molecular Techniques**

Plasmid preparations from clinical isolates and their transconjugants were used as templates in polymerase chain reaction (PCR) assays. Genes related to blaTEM, blaSHV, blaCMY-1, blacMPC, and blactx-M-1 were amplified with the oligonucleotide primers as described (23). Primers 5’-ATAAAAATCTTGAA-GACGAAA-3’ and 5’-GACAGTTACCAATGCTTAATCA-3’, corresponding to nucleotides -5 to 15 and 1,074 to 1,053, respectively, of the blatem structural gene (32), were used to amplify the entire sequences of blatem-related genes. Primers AmpC-1C (5’-CTGCTCTGACAGCCTTTCTT-3’) and AmpC-1B (5’-TTTTCAGAATGCGGCAAGC-3’) (23), which correspond to nucleotides 28-47 and 1,136-1,117, respectively, of the blacMPC2 structural gene (33), were used to amplify an internal fragment of approximately 95% of blacMPC-2-related genes. Both strands of the amplified products were sequenced on an ABI PRISM 310 automated sequencer (Applied Biosystems, Foster City, CA). Colony hybridization and Southern hybridization were performed as described (34,35) with DNA probes prepared from the PCR-generated amplicons. The probes were labeled with [α-32P]dCTP (Amersham Pharmacia Biotech) by using the random priming technique with a commercial kit (GibcoBRL Life Technologies, Gaithersburg, MD).

The genetic relatedness of ceftriaxone-resistant Salmonella isolates was investigated by ribotyping by using the method described by Popovic et al. (36). The chromosomal DNA was extracted and digested overnight with 10 U of SphI and PstI or EcoRI (Roche Molecular Biochemicals) (36,37). A cDNA probe was prepared by reverse transcription of 16S plus 23S rRNA (Roche Molecular Biochemicals) and was labeled with [α-32P]dCTP. DNA molecular marker II (Roche Molecular Biochemicals) and 1-kb molecular marker (Promega Corp., Madison, WI) were used as size standards.

**Results**

**Emergence of Salmonella Isolates Producing CMY-2-Like Enzymes**

Six of 384 Salmonella isolates displayed intermediate resistance to ceftriaxone by the disk diffusion method. The isolates were recovered from stool samples of two patients who had community-acquired enteric infections in August and November 2000, respectively, which were identified as S. enterica serovar Typhimurium. One isolate from each patient (isolates ST275/00 and ST595/00) was investigated further. Both isolates demonstrated reduced susceptibilities to cef-tazidime (MIC 64 µg/mL), cefotaxime (MIC 16 µg/mL), ceftriaxone (MIC 32 µg/mL), cefotixin (MIC 128 µg/mL), and amoxicillin-clavulanic acid (MIC 64 µg/mL) and were susceptible to imipenem (MIC 0.25 µg/mL). Both isolates were susceptible to ciprofloxacin and trimethoprim-sulfamethoxazole by the disk diffusion method. Isolate ST275/00 was resistant to chloramphenicol, while isolate ST595/00 was susceptible. Isoelectric focusing showed that both isolates expressed two β-lactamases focusing at pIs 5.4 and 9.0, suggesting that they produced a TEM-1–like enzyme and an AmpC-like β-lactamase. Both isolates yielded an approximately 1.1-kb DNA fragment in PCR with primers for blacMPC–like genes, and the amplified sequences obtained by nucleotide sequencing were identical to the homologous region of blacMPC2, which encodes a class C extended-spectrum cephalosporinase (33). A narrow-spectrum β-lactamase gene, blatem (18) was also detected by PCR and nucleotide sequencing in both isolates. The two ceftriaxone-resistant Salmonella isolates had different ribotypes, suggesting that they are of different clones (Figure 1).

**Prevalence of the blacMPC-2-Like Gene in E. coli and K. pneumoniae Isolates**

We found that 659 of 5,520 E. coli and 409 of 3,680 K. pneumoniae isolates showed resistance to at least one extended-spectrum cephalosporin by the disk diffusion test. These isolates were subjected to colony hybridization and PCR.
assays. Of these isolates, 97 E. coli isolates from 48 patients and 4 K. pneumoniae isolates from 2 patients gave a strong signal in colony hybridization with the blaCMY-2 probe and gave positive results in PCR with the primers for blaCMY-2. Sequence analysis indicated that the sequences of all amplicons were identical to the homologous region of blaCMY-2. The prevalence rates of CMY-2-like enzyme producers in E. coli increased from 0% in 1997 and 1998 to >4% in late 2000 (Figure 2). Among the patients with E. coli isolates, the incidence of patients with blaCMY-positive isolates increased from 0.0% in 1997 and 1998 to 3.6% in late 2000 (Figure 2).

The sources of E. coli isolates harboring a blaCMY-2-like gene and the infections associated with these isolates are summarized in the Table. The isolates and patients are distributed according to the likely locations of infection or colonization. Of the 97 blaCMY-positive E. coli isolates, 8 isolates were likely acquired in the community by eight patients. Six of these patients had never been hospitalized, and two had been hospitalized 10 months or 2 years before isolation. K. pneumoniae isolates producing the CMY-2-like enzyme were associated with nosocomial bloodstream infections in two patients. Notably, E. coli (EC811/00) and K. pneumoniae (KP218/00) isolates were recovered from the blood sample of a single patient.

Conjugation Experiments and Plasmid Analysis

One isolate from each patient was subjected to conjugation experiments and plasmid analysis. The blaCMY-positive plasmids were successfully transferred to E. coli C600 from 2 Salmonella isolates, 40 of 48 E. coli isolates, and 2 K. pneumoniae isolates. All E. coli transconjugants and their plasmid donors showed decreased susceptibilities to ceftazidime (MIC >32 µg/mL), cefotaxime (MIC >16 µg/mL), ceftriaxone (MIC >32 µg/mL), and cefoxitin (MIC >64 µg/mL). The sizes of the transferred plasmids ranged from approximately 65 kb to >100 kb.

Restricted by EcoRI, the plasmids from transconjugants of E. coli isolates showed 19 restriction patterns, designated TP1-TP19 (Figures 3A and 3C). Patterns TP17 (lane 17) and TP19 (lane 19), the most common patterns, were shown by 6 and 17 transferred plasmids, respectively. Of the 17 isolates with a TP19 plasmid, 3 were acquired from nursing homes and 5 from the community. Of the six isolates with a TP17 plasmid, two could have been acquired from the community. We considered that the remaining isolates with a TP17 or TP19 plasmid were acquired in the university hospital. Each of the remaining 17 patterns was shown by a single transferred plasmid. The TP19 pattern is the only restriction pattern displayed by transconjugants of all three studied bacterial species: Salmonella (lane 21), K. pneumoniae (lane 22), and E. coli (lane 24). Notably, K. pneumoniae isolate KP218/00 and E. coli isolate EC811/00, from the same patient, both had a TP19-type plasmid. The plasmids from transconjugants of Salmonella isolate ST275/00 (lane 20) and another K. pneumoniae isolate KP1905/00 (lane 21) showed two distinct restriction patterns. The presence of the blaCMY-2-like gene on plasmids was confirmed by Southern hybridization with the blaCMY-2 probe (Figures 3B and 3D).

Discussion

Emergence of ceftriaxone-resistant salmonellae has become a great public health concern worldwide (5-17). In
Taiwan, no ceftriaxone-resistant isolates were detected from several surveys, which included isolates collected from 1989 to 1998 (4,20,21). One of the surveys was conducted in National Cheng Kung University Hospital (4), and one survey conducted in 1998 included isolates from 22 hospitals (21). In the present study, *Salmonella* isolates resistant to extended-spectrum β-lactams were not detected until August 2000. Thus, the appearance of ceftriaxone-resistant *Salmonella* strains is likely a recent event.

Production of a CMY-2–like β-lactamase was responsible for resistance to extended-spectrum β-lactams in the *Salmonella* strains we isolated. The spread of *bla*<sub>CMY-2</sub> in *Salmonella* recently was reported to be an emerging problem in the United States (14,15). In Taiwan, the *bla*<sub>CMY-2</sub>-like gene was first detected in *E. coli* isolates collected in 1999 in the university hospital (23). The fact that the *bla*<sub>CMY-2</sub>-like gene was found in few isolates from patients with community-acquired infections suggested that the genetic determinant had spread in the community environment (23). The appearance of the *bla*<sub>CMY-2</sub>-like gene in the *Salmonella* isolates supports our previous speculation on the spread of the genetic determinant in the community environment. Moreover, the discovery of patients who might have acquired *E. coli* isolates with the CMY-2–like enzyme from nursing homes and in the community (Table) suggests widespread distribution of the *bla*<sub>CMY-2</sub>-like gene in southern Taiwan.

Conjugation experiments and plasmid analysis demonstrated the prevalence of conjugative resistance plasmids TP17 and TP19 among *E. coli* isolates. These *E. coli* isolates were recovered from patients hospitalized in the teaching hospital, transferred from nursing homes, or without recent hospitalization histories (Figure 3). Furthermore, the TP19 plasmid was found in a *Salmonella* strain and a *K. pneumoniae* strain, which suggests the interspecies spread of the *bla*<sub>CMY-2</sub>-like gene among different health-care settings and the community in Taiwan. The dissemination of the resistance determinant is probably partly because of horizontal transfer of endemic resistance plasmids.

All *K. pneumoniae* isolates producing the CMY-2-like enzyme were acquired by patients hospitalized in the university hospital. Producers of the CMY-2–like enzyme in *K. pneumoniae* were not found until 2000 and, even then, remained very rare (38). Isolate KP218/00 (lane 22, Figure 3C) and *E. coli* isolate EC811/00 (lane 24, Figure 3C) were obtained from the same patient, and both isolates had a TP19 plasmid, suggesting interspecies spread of a resistance plasmid. Thus, the acquisition of the *bla*<sub>CMY-2</sub> gene by *K. pneumoniae* in this hospital was likely also a recent event, which occurred after spread of the resistance determinant.

Enterobacteriaceae with plasmid-encoded class C cephalosporinases are typically resistant to cephamycins, extended-spectrum cephalosporins, and monobactams (19). No standard methods exist to detect class C cephalosporinases (39). Failure to detect and report CMY-2–like enzyme producers, and a lack of infection control measures against such organisms might be partially responsible for the rapid spread of the *bla*<sub>CMY-2</sub>-like gene in *E. coli* and the increased cases of infections caused by such organisms in our hospital (Table). With the discovery of *Salmonella* isolates producing the CMY-2-like enzyme in Taiwan, our study suggests that the cephalosporinase could become an emerging threat, not only to hospitalized patients, but also to public health. Constant and consistent surveillance is needed to prevent its further spread.
